13. Very like *Sch. albus* in ſtature, ſize, appearance and place, yet different in its glomerate brown ſpikelets, not faſtigiate, and white: it alſo flowers earlier [q].

Linneus firſt inſerted this in the appendix to his *Species Plantarum*; and it has been continued ſince, even by Willdenow. Dr. Smith has aſcertained that it is no more than a variety of *Sch. albus*, *n.* 37. which ſee.

14, 15, 16. Natives of the Cape of Good Hope.

17. Culms even, a foot high. Spike terminating, compoſed of ſeveral, commonly ſix, heaped together. Spikelets two at each tooth of the rachis, ſeſſile, equal, ovate, ferruginous. Calyx diſtich imbricate with ſeveral barren ſcales; the inmoſt pair bearing two flowers. Petals two, very ſmall, awl-ſhaped, with diſtant valves. Stamens three, white, longer than the calyx. Germ with a filiform ſemitrifid ſtyle. Floral leaf under the loweſt pair of ſpikelets, linear or awl-ſhaped, erect, longer than the whole ſpike.—Native of the Cape of Good Hope [r].

18, 19. Natives of the Cape of Good Hope.

20. Culm two feet high, without joints. Stem-leaves few, filiform, even, a foot long, looſe, channelled, acute, with a ſtriated ſheath browniſh at top. Floral leaves two, alternate, not exceeding the culm, with a widening ferruginous ſheath. Peduncles from each ſheath commonly two, looſe and almoſt membranaceous, length of the ſpike. Spikes compound, dark-ferruginous, oblong, awned, with an awned bracte of the ſame colour, commonly exceeding the ſpike. It differs manifeſtly from *Sab. glomeratus*, by its oblong ſpikes.—Native of the Cape [s].

21. Native of the Cape of Good Hope.

22. Roots many, heaped, appearing to be bulbous with brown inflated coats, putting forth long perpendicular fibres. Leaves linear, looſe, often exceeding the culm; which is about a foot high. Head ſpiked, ſhort, with a round rachis. Spikelets ſeveral, with about five ovate, hollow, ſcarioſe ſcales. Involucre five-leaved; the leaflets decreaſing, the longeſt being nine lines, and the ſhorteſt being ſix lines in length. Suppoſed to be native of Ceylon; found by Koenig [t].

23. Root perennial. Plant a foot high or leſs. Culm ſingle, upright, ſtriated, ſmooth, ſheathed with leaves at the baſe, roundiſh but bluntly three-cornered towards the top. Leaves almoſt the length of the culm, erect, linear, acuminate, entire, ſtriated, ſmooth. Sheaths ſurrounding the culm, hirſute or ciliate at the neck. Involucre manifold or three-fold. Leaflets very long, ternately alternate, ſpreading, linear-lanceolate, ſeſſile, ſtriated, ſmooth, towards the baſe ſnow-white or white coloured. Spikes terminating, cluſtered, ſeſſile, ſmall, oblong, acuminate, whitiſh. Chaffs or glumes in bundles, imbricate, ovate, acute, concave, ſcarcely keeled, entire, one-flowered. Filaments three, the length of the glumes, upright. Germ roundiſh. Style longer than the glumes, cloven to the middle. Stigmas ſhort, erect. Seed roundiſh, flatted a little, large. It reſembles the *Kyllingias*, and is probably mixed with them by authors, eſpecially with *Kyllingia triceps*.—Native of the Weſt Indies [u].

24. Root bulbous, covered with the rudiments of fallen leaves. Leaves numerous, briſtle-ſhaped, ſtriated, erect, almoſt the length of the culm, ſeparated at the baſe by white membranaceous ſcales. Culms a ſpan high, leafleſs, ſubtriquetrous, ſcarcely longer or wider than the leaves. Flowers red, glomerate, ſmall, in three or four little ſeſſile alternate balls towards the top of the culm. Under each little ball is a briſtle-ſhaped leaf longer than the ball. It has the appearance of *Juncus bulboſus*.—Native of the Cape of Good Hope [x].

25. Native of the Cape of Good Hope.

26. Diſtinct from *Scirpus cepholates*. Native of Surinam.

27. Two feet high. Culm ſtriated, ſmooth. Leaves ſheathing, half a foot long, linear, keeled, ſtriated, ſmooth, with the keel of the leaves ſubſerrate. Spikes terminating, umbelled. Peduncles from the ſheaths of the terminating leaves ſeveral, unequal, three-ſided. Involucre none, but only the two alternate leaflets, from the ſheaths of which the peduncles riſe. Spike-

lets

Digitized by Google

lets in little terminating balls (ſometimes compound) very much crowded, ſeſſile, acuminate, ſpreading, ferruginous. Glumes chaffy, heaped, unequal, ſubimbricate; the inner ones more tender, narrower, leſs, one-flowered. Filaments three, very ſhort. Germ extremely ſmall. Style longer than the glumes, trifid at the top, permanent. Stigmas capillary, cirrhoſe. At the baſe of the germ are two briſtles the length of the glumes. Seed incloſed within the glumes, obovate, moſtly obcordate, bluntly three-cornered, ferruginous, ſmooth.

It is not a *Cyperus*, becauſe the chaffs are not diſtich, and the ſeed is not three-ſided. It is very different from the *umbellatus*, figured by Jacquin in his *Icones rariores*, and deſcribed by him in the firſt volume of his *Collectanea*: that having altogether the appearance of a *Cyperus*, and a many-leaved terminating involucre [y].—Native of Jamaica.

28. Root perennial. Culm a foot high, erect. Leaves linear, ſmooth, keeled, numerous on the culm; the upper ones longer than the umbel. Branches of the umbel unequal. Spikelets the ſize of Muſtard ſeed, three always glomerate ſeſſile. Scales ovate acuminate nerved brown. Univerſal involucre many-leaved, unequal, with one leaflet longer than the umbel, but the reſt much ſmaller. It has no partial involucre. It is difficult to decide from a ſhort deſcription how far it differs from the preceding: but it is certainly very different from Jacquin's *umbellatus* [z].—Native of North America.

29. Native of Jamaica and North America. Thunberg's plant ſeems, in Willdenow's opinion, to be different from Linneus's.

30. Culm eight or ten feet high, ſingle, jointed, ſmooth, ſtriated. Leaves ſheathing, very long, keeled, half an inch wide, cartilaginous-ſerrate along the back and edge, ſtriated, ſmooth, rigid: ſheaths cloſed in front, ſerrate. Flowers in lateral panicles from the ſheaths. Peduncles ſolitary, ſhort, compreſſed, ſheathed; ſheaths numerous, crowded, alternate, from which ſpring ſome partial peduncles, which are elongated, looſe, diffuſed, towards the top next the ſheathlet ſubdivided into many unequal umbelled pedicels, frequently terminating in an umbellet, with the ultimate pedicels three-flowered. Spikelets three or four, ovate, acuminate, ſmall, ferruginous. Glumes or ſcales oblong, acute, unequal: at the ſide of the inner glume ſurrounding the germ are capillary briſtles the length of the glume. Filaments very ſhort. Germ linear-oblong. Style longer than the glumes, trifid. Stigmas reflexed, convolute, permanent. Seed ovate, acute, ſhining brown.

It is allied to Sch. Mariſcus, and was formerly taken for a variety of it by Linneus: but the culm is higher and bluntly three-ſided; the panicle very large, with peduncles and pedicels longer and filiform; the ſpikelets ſmaller and ferruginous.

Native of Jamaica, in ſea marſhes [a].

31. This alſo is a native of Jamaica, and it was gathered by Houſtoun in the ſalt marſhes near La Vera Cruz. Swartz gave it as a diſtinct ſpecies in his Prodromus, being intermediate between the preceding and *Mariſcus*. But in his deſcriptions he ſays that it reſembles the latter ſo nearly, that he dares not any longer to propoſe it as a diſtinct ſpecies.

32. Almoſt a fathom in height. Culm jointed, erect, ſtriated: joints ſwelling. Leaves ſheathed at the baſe, long, wide, linear, quite entire, very finely ſtriated longitudinally, rigid: ſheaths ancipital, finely ſtriated. Panicles burſting from ancipital-lanceolate cowled ſheaths, ſubdivided into dichotomous ſubfaſtigiate diffuſed branchlets, having ſheathlets underneath at all the diviſions, of a red-ferruginous colour. Spikelets ſolitary or in pairs, ſeſſile, two-flowered, polygamous, on prickly-ſerrate peduncles. Glumes four-valved, two-flowered: valves decuſſated, ovate, acute, concave, ſlightly keeled, ſometimes ſerrate, brown. Filaments none. Germ three-cornered. Style long, trifid at top. Stigmas cirrhoſe. Serrate briſtles are placed upon the piſtil. One of the florets is ſmall, interior and two-valved; the valves equal and lanceolate. Filaments two or three minute. Piſtil ſmall.—Native of the Weſt Indies.

Though it approach very near to this genus, and particularly to *Mariſcus*, yet it is ſo ſingular, and ſo different in habit, that it might make a diſtinct genus if ſufficient characters could be found.

33. From one to four feet high, growing in tufts. Culms ſimple, ſharply three-ſided, rugged, leafy below. Leaves ſheathed, very long, equal to the culm or longer, flattiſh, ſlightly keeled, ſtriated, linear, ſerrate-prickly along the keel and edge, ſtiffiſh; the upper ones ſhorter and diſtant: ſheaths alternate, crowded, keeled, with a blunt dagger-point in front. Corymbs peduncled, lateral, compound, ſhorter than the leaves, before flowering crowded, nodding, afterwards divaricating: peduncles elongated, from the ſheaths of the upper leaves, ſolitary, remote, looſe; the upper ones crowded. Spikelets cylindrical-ſubulate, very ſhortly pedicelled, patulous, ferruginous. Bractes capillary, longer than the florets, at the baſe of the pedicels. Lower glumes ſhorter, ovate, imbricate: upper a little longer, and between them a middle flower male and ſolitary, between the outer ones females or an hermaphrodite. Filaments three very ſhort. Anthers linear. Germ ovate, margined, blackiſh, ſurrounded at the baſe with from two to four jointed briſtles. Style long, undivided. Stigma linear. Seed roundiſh, black-ruſt-coloured.—Moſt commonly many of the ſpikelets are male, without any females. Rottboell's figure is but indifferent, but the parts of fructification are accurately drawn. The habit, and affinity of this ſpecies to *Sch. Mariſcus*, place it rather in this genus than in that of *Scirpus*, where it ſtands in *Syſtema Vegetabilium*.

Native of the Weſt Indies, in Jamaica and Surinam: alſo in the Eaſt Indies and China [b].

34. Root perennial. Culms ſix feet high, the thickneſs of a ſwan's quill, ſtiff, ſomewhat woody, even. Leaves ſheathed, ſtrict, even, erect. Heads alternate, towards the top of the culm, ſubſeſſile, each from a leafy ſheath ſcarcely longer than the head. Each head is compoſed of ſmaller heads, and theſe of ſmaller yet till we come to the proper flower, divided by a leafy mucronate ſcale. Glume four-leaved: leaflets in pairs, oppoſite, oblong, membranaceous: the inner pair very thin and blunt. Stamens three, filiform, membranaceous; with anthers ſtanding out the length of the flower. Germ very ſmall. Style filiform. Stigmas three, filiform.

Native of the Cape of Good Hope, where it was found by Koenig [c].

35, 36. Natives of the ſame Cape.

37. Root perennial, creeping. Culms half a foot high, aſcending, ſtriated, ſmooth, divided at top into upright flowering-branches, ſheathed at the baſe by wide concave ſcales. Almoſt all the leaves on the ſtem, alternate, ſheathing, linear, bluntiſh, a little recurved, ſmooth, never exceeding the ſtem: ſheath entire. Flowers in terminating erect bundles, ſubcorymbed, pedicelled, ſnow-white, becoming browniſh after flowering. In the variety, which Linneus and others made a ſpecies under the name of *fuſcus*, always brown. Bractes like the leaves, but ſhort [d]. Dr. Stokes remarks, that it has two ſtamens, ſeldom three.

β. Dr. Smith, in comparing the original ſpecimens in the Linnean herbarium, has not been able to diſcover the leaſt difference between the white and brown-headed Bog-ruſh. He remarks, that they have both three-ſided culms, though Linneus has placed his *fuſcus* among the round ones.

Native of Europe, in bogs. Near Gamlingay park in Cambridgeſhire. Ampthill moor, Potton and Aſpley, Bedfordſhire, *Mr. Abbott*. Felthorpe bogs, and near Haydon, Norfolk, *Mr. Bryant*. Birmingham heath. New Foreſt. About Kendal. Bagſhot heath. Between Wickham and Croydon in Surry. Near Tunbridge in Kent. Common in Cornwall, Lancaſhire, Weſtmoreland, Cumberland, and Scotland. It flowers in july and auguſt.

[y] Swartz. [z] Willdenow. [a] Swartz. [b] Swartz. [c] Lin. mant. [d] Smith.

Digitized by Google

38. Height from three to ſix feet. Culm very long, ſimple, looſe, ſtriated. Leaves linear, very long, ſeſſile, keeled, ſtriated, ſerrate. Spikes axillary. Peduncles ſolitary, elongated, filiform. Spikelets in bundles, ſmall, ſix to ten, unequal, round and linear, ſeſſile, ferruginous, ſmooth. Glumes chaffy, many, unequal: the loweſt ſmall; the reſt convex, acuminate, imbricate; the interior ones more tender, ſmaller, one-flowered. Filaments three, very ſhort. Germ roundiſh. Style awl-ſhaped, ſcarcely longer than the glumes, trifid. Stigmas capillary, reflexed. Seed three-cornered, very ſmall, ferruginous.—Native of Jamaica, in the woods on the higheſt mountains.

39. Height about a foot. Culm ſimple, ſetaceous, weak. Leaves moſtly ſhorter than the culm, ſomewhat ſtriated, erect. Culms towards the upper part ſimply two-parted or ſubdichotomous, into axillary, peduncled, aggregate ſpikelets, three to ſix in number, awl-ſhaped and ſmall. Lower peduncles often ſolitary, an inch long: upper crowded, bundled, very ſhort. Lower glumes ſmaller, ovate, acute, keeled, terminated by a very ſhort awn: upper glumes lanceolate, awnleſs, convolute at the top. Filaments two, very ſhort. Style bifid. Stigmas capillary. At the ſides of the germ are two capillary briſtles, the length of the glume. Seeds roundiſh, compreſſed at the edge, acuminate, tranſverſely wrinkled.

Native of the Weſt Indies, in dry paſtures. Jamaica. Found at Surinam by Rolander; from whoſe collection Bergius and Rottboell had their ſpecimens.

40. Height about an inch. Roots capillary, ſimple. Culms almoſt upright, capillary. Leaves radical, equalling the culm, filiform, keeled at the baſe, ſheathing, ciliate at the edge, ſtriated, ſmooth. Spikelets three or four, very ſmall, one above another, ovate, acuminate. Under the loweſt ſpike is an awl-ſhaped leaflet, ſheathed at the baſe. Glumes chaffy, heaped, imbricate, ſeparating the flowers, ovate, keeled, awnleſs, one-flowered. Filaments three, the length of the chaffs. Anthers linear. Germ roundiſh. Style filiform, three-ſided at the baſe, trifid at top. Stigmas capillary, reflexed. Seed roundiſh, bluntly three-cornered, rugged, ferruginous, appearing as it were echinate, when examined by a microſcope; without which the parts of fructification are not viſible.—Native of Jamaica in the ſouthern parts.

41. About a foot high. Roots filiform, creeping a little. Culms in bundles, crowded, filiform. Leaves equalling the culm, ſheathing at the baſe, linear with convolute margins, looſe, lightly ſtriated. Spikelets terminating, three-ſided, awl-ſhaped, from reflex ſpreading. Involucret two or three-leaved: upper leaflet much the longeſt; the third very ſmall and often wanting. Glumes imbricate, ovate acuminate keeled, ferruginous, almoſt equal, ſtriated. Stamens one, two or three very ſmall. Style trifid. Stigmas very ſhort, reflexed. Seed ovate-three-cornered, ſmooth, ferruginous. Receptacle or rachis permanent, warted from the ſpikelets that have fallen off.—Native of Hiſpaniola; flowering in ſpring[e].

Five new ſpecies of *Schoenus* are deſcribed in Vahl's *Eclogæ Americanæ*.

Schoenus. See *Carex*, *Cryptis*, *Cyperus*, *Kyllingia*, *Reſtio*, *Scirpus*, *Scleria*.

Schoenus coloratus. See *Kyllingia monocephala*.

——— odoratus. *Gmel.* is *Kyllingia triceps*.

Loureiro has a *Schoenus* under the name of *coloratus*, which Willdenow thinks to be a different ſpecies from the *coloratus* of Linneus. He alſo has a *Schoenus ruber*. Both are natives of Cochinchina.

SCHOEPFIA. (*So named by Schreber, in honour of Johann David Schoepf, Preſident of the medical college at Anſpach, author of* Materia medica Americana, &c.)

Lin. gen. Schreb. n. 325. Codonium. *Vahl.*

Claſſ. 5. 1. Pentandria Monogynia.

Nat. order of *Aggregatæ*. *Caprifolia*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* incruſting the germ at bottom, turbinate-angular indiſtinctly five-toothed.

COR. one-petalled, bell-ſhaped, ten-grooved at the baſe, five-cleft: *ſegments* triangular, acute, reflexed.

STAM. *Filaments* five, very ſhort. *Anthers* twin, erect, in the mouth of the corolla.

PIST. *Germ* turbinate, half inferior, within the corolla, crowned with a ſemiglobular porous *gland*. *Style* ſhorter than the corolla, cylindrical, erect. *Stigma* capitate, trifid.

PER. *Drupe*, with a one-celled nut.

SEED one.

ESSENTIAL CHARACTER.

Cal. double; outer bifid, inferior; inner ſuperior, quite entire. *Cor.* bell-ſhaped. *Stigma* capitate. *Drupe* one-ſeeded.

SPECIES.

1. Schoepfia americana.

Lin. ſpec. ed. Willd. 1. 996.

Codonium arboreſcens. *Vahl ſymb.* 3. 36. *act. hafn.* 2. 1. 206. *t.* 6.

DESCRIPTION, *&c.*

It is a ſmall tree eight or ten feet in height, with round ſmooth branches. Leaves petioled, alternate, ovate, very ſmooth, attenuated, blunt, quite entire. Peduncles axillary, often in pairs, one-flowered, but ſometimes two or three-flowered. Calyx double; one inferior, one-leafed ſubbifid, the other half-ſuperior entire. Sometimes there are only four ſtamens. The genus is allied to *Lonicera* and *Loranthus*.

Native of Santa Cruz and Montſerrat, where it was found by von Rohr[f].

SCHONGA-CUSPI. See *Clitoria*.

SCHORIGERAM. See *Clitoria*.

SCHOTIA. (*So named by Jacquin, from Richard vander Schot, his companion in his travels.*)

Lin. gen. Schreb. n. 705. *Jacqu. collect.* 1. 93. *Juſſ.* 347. Theodora. *Medic. monogr.* 1786. Guajaci ſpecies. *Linn.*

Claſſ. 10. 2. Decandria Mongynia.

Nat. order of *Lomentaceæ*. *Leguminoſæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, coloured: *tube* turbinate, ſubcompreſſed, fleſhy, permanent: *border* half-five-cleft; *ſegments* ovate, concave, blunt, erect, equal.

COR. *Petals* five, placed on the tube of the calyx, oblong, concave, blunt, erect, equal, lying over each other at the ſides, ſeſſile, twice as long as the ſegments of the calyx.

STAM. *Filaments* ten, awl-ſhaped, erect, a little longer than the petals, inſerted in a ring into the tube of the calyx. *Anthers* oblong, incumbent.

PIST. *Germ* oblong, compreſſed, pedicelled. *Style* filiform, length of the ſtamens. *Stigma* ſimple, blunt.

PER. *Legume?* pedicelled.

SEEDS two. *Medicus*.

ESSENTIAL CHARACTER.

Cal. five-cleft. *Petals* five, inſerted into the calyx, cloſed by the ſides lying over each other. *Legume* pedicelled.

SPECIES.

Involucre quite entire, calyx toothed, leaves acuminate.

DESCRIPTIONS, *&c.*

1. This is a climbing paraſitical ſhrub, with ſquare branches covered by an aſh-coloured bark. Leaves oppoſite roundiſh-elliptic quite entire coriaceous bluntiſh petioled. Peduncle terminating, an inch and half long. Flowers in heads. Involucre coriaceous one-leafed five-cleft containing about fifteen flowers, ſegments roundiſh blunt. Calyx bell-ſhaped coriaceous permanent, with the margin truncate and quite entire. The number of ſegments in the corolla and of the ſtamens varies from five to ſix[g].

Diſcovered in the high mountains of the iſland of Montſerrat, by Ryan[h].

2. Involucre one-leafed truncate four-cornered ſmooth thick containing from four to eight aggregate flowers. Perianth one-leafed ovate-campanulate erect, a little longer than the involucre undivided ſubtruncate, with eight very ſmall toothlets. The leaves are thinner and much more acute. The number eight is more frequent in this, five, ſeven, nine, ten more rarely.—Native of Jamaica[i].

SCHRANCKIA *quinquefaria* of Gmelin, *ſyſt.* 515. *Scop. introd.* 1043. is Goupia of Aublet[k]: which ſee under *Gloſſopetalum*.

SCHREBERA. (*So named in honour of Jo. Chriſtian Dan. Schreber, Profeſſor of Phyſic, &c. at Erlang, editor of Linneus's* Genera Plantarum, *and author of many works in Botany.*)

[g] Willdenow. [h] Vahl. [i] Swartz and Willdenow. [k] Dryander in Linn. tranſ. 2. 229.

SPECIES.

1. Schrebera ſwietenioides.
Roxb. corom. 2. *p.* 2. *t.* 101.

DESCRIPTION, *&c.*

Trunk erect, with a ſcabrous bark. Branches numerous, ſpreading in every direction, ſo as to form a large beautiful ſhady head. Leaves nearly oppoſite, on round ſmooth petioles; pinnate with an odd leaflet, about a foot long. Leaflets three or four pairs, oppoſite, on ſhort pedicels; the loweſt largeſt and obliquely ovate, whilſt thoſe towards the apex become more lanceolate: all are entire, pointed, ſmooth on both ſides, and three or four inches long. Panicles terminating, thin, trichotomous. Bractes ſmall, falling. Flowers white and brown variegated, very fragrant during the night. Capſule large, the ſize of a pullet's egg.

It is a large timber tree, a native of vallies in the mountainous parts of the Rajahmundry Circar; flowering about the beginning of the hot ſeaſon. The wood is of a gray colour, very cloſe-grained, heavy and durable. It is reckoned leſs ſubject to crack and warp than any other; on which account it is employed by weavers in many parts of their looms, particularly for the beam: it ſerves alſo for a great variety of other uſes; and probably would anſwer well for ſcales to mathematical inſtruments. Though not ſo handſome as Box, it is leſs ſubject to warp.

SCHREBERA SCHINOIDES of Linneus, is a ſpecies of *Cuſcuta*, growing on *Myrica æthiopica*.

——— ALBENS of Retzius (*obſ.* 6. 25.) *Celaſtrus glaucus* of Vahl (*ſymb.* 2. 42.) is a ſpecies of *Elæodendrum*.

——— SCHINOIDES of Thunberg's prodromus, is Hartogia capenſis. *Linn. ſuppl.* 128. *Thunb. nov. gen.* 87[l].

SCHUNDA PANA. See *Caryota*.

SCHUNUMPI VALLI. See *Ciſſus*.

Claſſ. 14. 2. Didynamia Angioſpermia.
Nat. order of *Perſonatæ*. *Schrophulariæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, tubular-ventricoſe, ſtriated: *mouth* four-cleft, oblique: *upper ſegment* very ſhort; *lateral* ones longer; *loweſt* ſtill longer, wider, emarginate.

COR. one-petalled, ringent: *tube* length of the calyx: *border* erect: *upper lip* erect, concave, quite entire: *lower lip* of the ſame length, trifid, blunt, the little ſegments equal.

STAM. *Filaments* four, filiform, length of the corolla, of which two are a little ſhorter. *Anthers* incumbent.

PIST. *Germ* roundiſh. *Style* in the ſame ſituation and of the ſame form and length with the ſtamens. *Stigma* thickiſh, recurved.

PER. *Capſule* ovate, compreſſed, two-celled, two-valved: *partitions* folded.

SEEDS very many, chaffy, lanceolate, ſmall. *Gærtn.*

ESSENTIAL CHARACTER.

Cal. four-cleft; the upper lobe very ſmall; the loweſt very large and emarginate.

SPECIES.

1. Schwalbea americana.
Lin. ſpec. 844. *ſyſt.* 551. *Reich.* 3. 114. *mant.* 414. *Gron. virg.* 92. *Pluk. mant. t.* 348. *f.* 2? (Euphraſia.)

DESCRIPTION, *&c.*

Stem quite ſimple, four-cornered, pubeſcent. Leaves lanceolate, pubeſcent. Flowers alternate, ſeſſile. Calyx pubeſcent. Corolla dark-red, inclining. The fructification wants to be farther examined, Gronovius's ſpecimen not being ſufficient for that purpoſe[m].—Native of North America.

Gærtner deſcribes the capſule as elliptic-acuminate, ſmooth, with an indiſtinct groove on each ſide, two-celled,

[l] Roxburgh, corom. [m] Linn. mant.

Digitized by Google

two-valved; the valves when ripe ſometimes bifid at the top: partition doubled, formed of the margins of the valves bent in. Receptacle oblong, narrow, compreſſed a little, not faſtened to the partition, but falling when ripe. Seeds very numerous, ſmall, chaffy, acuminate towards the umbilicus, widening outwards with the end rounded. Nucleus a little turgid in the middle of the ſeed on one ſide of it.

SCHWENKFELDIA. (*So named by Schreber, in memory of Caſpar Schenckfelt, a Sileſian phyſician, author of a catalogue of the plants and foſſils in Sileſia. Lipſ.* 1601. *He died in* 1609.)

Lin. gen. Schreb. n. 306. & *p.* 822. Sabicea. *Aublet. t.* 75, 76. *Swartz prodr.* 46. *Juſſ.* 207.

Claſſ. 5. 1. Pentandria Monogynia.

Nat. order of *Rubiaceæ*.

GENERIC CHARACTER.

CAL. *Involucre* four-leaved.

Perianth one-leafed, five-parted, ſuperior, permanent: *ſegments* lanceolate, acute.

COR. one-petalled, funnel-form: *tube* long, ſlender: *throat* hirſute: *border* five-parted: *ſegments* lanceolate, acute.

STAM. *Filaments* five, inſerted into the tube of the corolla. *Anthers* parallelopiped, incumbent.

PIST. *Germ* inferior, ovate. *Style* filiform. *Stigmas* five, oblong.

PER. *Berry* globular, crowned with the calyx, five-celled.

SEEDS very many, very ſmall, faſtened to ſemilunar receptacles.

ESSENTIAL CHARACTER.

Involucre four-leaved. *Cor.* funnel-form. *Stigmas* five. *Berry* five-celled, many-ſeeded. (*Cor.* ſalver-form. *Stigma* five-parted. *Willd.*)

SPECIES.

1. Schwenkfeldia hirta.

Lin. ſpec. ed. Willd. 1. 982. *Swartz deſcr.* 1. 450. Sabicea hirta. *Swartz prodr.* 46.

Leaves ovate-lanceolate acuminate, flowers peduncled.

2. Schwenkfeldia cinerea.

Lin. ſpec. ed. Willd. 1. 982. *Swartz deſcr.* 1. 452. Sabicea cinerea. *Swartz prodr.* 46. *Aubl. guian.* 1. 192. *t.* 75.

Leaves oblong acute tomentoſe hoary beneath, flowers ſubſeſſile.

3. Schwenkfeldia aſpera.

Lin. ſpec. ed. Willd. 1. 982.

Sabicea aſpera. *Aubl. guian.* 1. 197. *t.* 76.

Leaves elliptic acuminate rough hoary beneath, flowers ſeſſile.

DESCRIPTIONS, *&c.*

1. This is a climbing ſhrub, branched, with the ſtem and branches ſtriated and hirſute. Leaves oppoſite, nerved, hirſute, on ſhort, round, hirſute petioles. Stipules large, interpoſed between the petioles, wide, cordate-ovate, membranaceous, whitiſh. Peduncles axillary, from the boſom of the ſtipules, ſhorter than the petioles, umbelliferous. Umbellets three-flowered. Involucret one-leafed four-cleft; ſegments ovate, ſpreading, rough-haired. Flowers pedicelled, white, void of ſcent. Segments of the perianth long, erect, ſtriated, rough-haired, permanent. Corolla funnel-form, with the tube twice as long as the calyx, and the border flat and five-cleft, with lanceolate patulous ſegments. Anthers linear, the length of the filaments. Style the length of the corolla. Stigma five-parted. Berry ſnow-white when ripe.

Native of Jamaica, in the weſtern parts of the iſland, in mountain woods, flowering in april.

2. This alſo is a climbing ſhrub, with the ſtem and branches round and hiſpid; the branchlets ſcattered, ſpreading, tomentoſe. Leaves oppoſite, decuſſated, ſoft beneath, nerved and veined. Petioles ſhort, tomentoſe. Stipules between the petioles, wide, ovate, membranaceous, villoſe. Flowers axillary, from three to five, ſubſeſſile, crowded, with a few ſmall whitiſh bractes between the flowers. Involucret four-parted, with the ſegments ovate and whitiſh-tomentoſe. Perianth villoſe. Corolla white: tube hirſute on the outſide: border five-cleft, with oblong acute ſegments. Filaments ſhort. Anthers oblong. Germ hoary. Stigmas five oblong. Berry villoſe, according to Aublet red when ripe.—Native of Cayenne and Guiana, in hedges [a].

3. The corolla of this is ſometimes four-cleft, accompanied by four ſtamens, and the berry three or four-celled [b].—Native of Guiana, on the banks of rivers.

SCHWENKIA. (*So named by van Royen, from Martin Wilhelm Schwencke, phyſician and profeſſor of botany at the Hague, who died in* 1785, *aged* 78.)

Lin. gen. Reich. n. 31. *Schreb. n.* 38. *Juſſ.* 123.

Claſſ. 2. 1. Diandria Monogynia.

Nat. order of *Luridæ*. *Scrophulariæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, tubular, ſtriated, ſtraight, five-toothed, permanent.

COR. one-petalled: *tube* cylindrical, length of the calyx; *border* almoſt regular, length of the calyx, inflated at the throat, five-plaited: plaits cloſing the orifice in form of a ſtar; with a glandular body growing upon the exterior angles of the plaits; the two upper ones longer than the glands.

STAM. *Filaments* five: *three* ſhorter, briſtle-ſhaped, caſtrated; *two* upper, longer, fertile. *Anthers* two, ovate, acute, two-celled.

PIST. *Germ* globular. *Style* ſimple, length of the ſtamens. *Stigma* obtuſe.

PER. *Capſule* compreſſed like a lens, ſmooth, longer than the enlarged calyx, two-celled, two-valved.

SEEDS very many, very ſmall, ſomewhat angular. *Receptacle* ſubglobular.

OBS. *In a natural order it approaches very near to* Browallia.

ESSENTIAL CHARACTER.

Cor. almoſt equal, with the throat plaited and glandular. *Stam.* three barren. *Capſ.* two-celled, many-ſeeded.

SPECIES.

1. Schwenkia americana. *Guinea Schwenkia.*

Lin. ſyſt. 64. *Reich.* 1. 48. *Willd.* 1. 106. *Schwenk. hort. med. Hag.* 1766. *edit. p.* 328. *t.* 1. *Ait. kew.* 1. 29.

DESCRIPTION, *&c.*

1. It is a biennial plant, with alternate leaves [a]: and axillary flowers. Native of Guinea. Introduced in 1781, by Meſſ. Kennedy and Lee. It flowers in auguſt and ſeptember [c].

SCHYBUM. See *Gundelia.*

DESCRIPTIONS, *&c.*

1. Root very large, ſomewhat pear-ſhaped, compoſed of many coats as in the Onion, and having ſeveral fibres coming out at the bottom, and ſtriking deep in the ground. From the middle of the root ariſe ſeveral ſhining leaves, a foot long, and two inches broad at their baſe, leſſening all the way to the top, where they end in points; they continue green all the winter, and decay in the ſpring: then the flower-ſtalk comes out, riſing two feet high, naked about half way, and terminated by a pyramidal thyrſe of flowers, which are white.

[Leaves lanceolate, ſtrict. Scape before the leaves, very long, many-flowered. Bractes linear-lanceolate, bent with a knee-joint in the middle, turned upwards, and having a ſpur beneath[t].

Bulb almoſt as big as the human head. Leaves ovate-oblong, blunt. Scape round, as thick as the little finger, upright. Raceme denſe, almoſt the length of the ſcape: each flower on a filiform pedicel, twice or thrice the length of the flowers. Bractes membranaceous, awl-ſhaped, erect. Stamens equal in length to the corolla. Capſule triangular[u].

Native of Spain, Portugal, Italy, Barbary, Syria, on ſandy coaſts. Desfontaines ſays it is common in Barbary, in fields; flowering in autumn. In England it flowers in april and may: and was cultivated in the botanic garden at Oxford, in 1648[t].]

There are two varieties, one with a red, the other with a white root; but the white is generally preferred for medicinal uſe: [Dr. Woodville on the contrary ſays, that the red-rooted variety has been ſuppoſed to be more efficacious; but remarks juſtly that this red colour is confined to the outer coats of the root.

It is very nauſeous, intenſely bitter and acrimonious, without any perceptible ſmell. Alkalines conſiderably abate the bitterneſs and acrimony: vegetable acids make little alteration in either; but the taſte of the acid makes that of the Squill more ſupportable.

This is one of the few medicines known in the early ages of Greece, which is held in great eſtimation and is in frequent uſe at this time; though it manifeſts a poiſonous quality to ſeveral animals; as appears from Hillefield, Bergius, Vogel, and others. If much handled, it exulcerates the ſkin; and in large doſes frequently repeated, it not only excites nauſea, &c. but ſtrangury, bloody urine, hæmorrhoids, &c. with fatal inflammation and gangrene of the ſtomach and bowels. Under proper management however it is a medicine of great practical utility. In dropſy it has long been eſteemed the moſt certain and effectual diuretic with which we are acquainted: and in aſthma or dyſpnoea, occaſioned by the lodgment of tenacious phlegm, it has been the expectorant uſually employed. In large doſes, it is apt to prove emetic, and ſometimes purgative, and thus the patient is deprived of its diuretic effects: it is given therefore in ſmall doſes repeated at more diſtant intervals, or an opiate is joined with it. From a continued repetition, the doſe may be gradually increaſed, and the intervals ſhortened: when thus the doſes come to be tolerably large, the opiate may be moſt conveniently employed to direct the operation of the Squill more certainly to the kidnies. In dropſy, when from an effuſion of water into the cavities, leſs water goes to the kidnies; it may be of uſe to add neutral ſalt.

Dr. Cullen recommends a ſolution of corroſive ſublimate to promote the diuretic effects of Squills. When the *primæ viæ* abound with mucous matter, and the lungs are oppreſſed with viſcid phlegm, Squills are in general eſtimation. As an expectorant they may be ſuppoſed not only to attenuate the mucus, and thus facilitate its ejection, but by ſtimulating the ſecretory organs and mucous follicles, to excite a more copious excretion of it from the lungs, and thereby leſſen the congeſtion, upon which the difficulty of reſpiration very generally depends. Therefore in all pulmonic affections, excepting thoſe of actual or violent inflammation, ulcer and ſpaſm, the Squill has been experienced to be a uſeful medicine.

The officinal preparations are a conſerve, the dried root, a ſyrup and vinegar, an oxymel, and pills. When this root is intended as a diuretic, it has moſt commonly been uſed in powder, with the addition of neutral ſalts, as nitre or cryſtals of tartar, eſpecially if the patient complained of much thirſt; others recommend calomel; and to render the Squills leſs offenſive to the ſtomach, it has been uſual to join an aromatic. The doſe of dried Squill is from two to four or ſix grains, once a day, or half this quantity twice a day. The doſe of the other preparations, when freſh, ſhould be four times this weight[x].]

2. This has a ſcaly root like the Lily, for which reaſon Tournefort ſeparated it under the name of *Lilio-Hyacinthus*. The root (or bulb) is oblong and yellow, very like that of Martagon: the leaves are ſhaped like thoſe of the White Lily, but are ſmaller. The ſtalk is ſlender, and riſes a foot high; it is terminated by blue flowers; which appear in june.—Native of Spain, Portugal, and the Pyrenees.

3. Bulb roundiſh, ſolid, like that of the Hyacinth. The leaves come out ſparſedly, and are very like thoſe of the Engliſh Hare-bells (Hyacinthus non-ſcriptus or Scilla nutans.) Stem ſeven or eight inches high, terminated by cluſtered flowers of a pale blue colour; at firſt diſpoſed in a ſort of umbel or depreſſed ſpike, but afterwards drawing up to a point and forming a conical corymb.

[Raceme conical-oblong with pedicels almoſt erect, the length of the flower. Flower ſpreading with petals bent back at the ſides, blunt at the top, white or blue. Bractes the length of the pedicels[x].

[t] Linn. ſpec. [u] Desfontaines. [t] Hort. kew.
[x] Woodville. [x] Linn. mant.

Bulbs

Bulbs cluſtered, coated. Scape a large ſpan high, round below, ſomewhat angular above. Leaves commonly rather longer than the ſcape, ſcarcely half an inch wide. Raceme conical, compoſed of from ſeven to thirty and more ſcattered, peduncled flowers. Bractes two to each peduncle, coloured, one longer, the other ſhorter than the peduncle. Corolla ſpreading very much; petals ovate, pale blue, with the ſides of the claws bent back. Filaments and anthers erect, blue. Piſtil blue: germ ſobglobular, ſix-grooved; ſtyle the ſame length with the ſtamens, linear, permanent; ſtigma minute. Capſule tricoccous, three-celled, ſix-valved, three-ſeeded [y].

By the trivial name this ſhould be a native of Italy; Linneus and Aiton aſſign no place for it: neither do Cluſius or Parkinſon. Miller affirms it to be a native of Portugal. Allioni ſays that it is found in the county of Nice. Retzius will have this to be Haller's Phalangium, n. 1212. which he found in the meadows near Berne; but Haller himſelf denies it. Cultivated here in 1629 [z].

4. Root bulbous. Leaves four, radical, ſpreading, cruciate, cordate-lanceolate, ſeſſile, nerved, even. Scape none. Flowers ſhorter by half than the leaves: peduncles filiform-ſetaceous, one-flowered, very abundant. Petals lanceolate, membranaceous at the edge. Filaments ſetaceous, ſhorter than the petals. Anthers oblong. Germ roundiſh, hexangular, obtuſe. Style filiform. Stigma obtuſe.

Native of Africa [a].]

5. Root large, ſolid, raiſed a little pyramidal in the middle, covered with a brown coat, from this come out before winter five or ſeven leaves, ſix or eight inches long, of a lucid green, keeled, and ſpreading almoſt flat on the ground. From the centre of theſe come out one, two or three ſcapes, thick, ſucculent, ſix or eight inches high, terminated by a conical corymb of flowers, upon pretty long pedicels.

[Bulb ovate, coated. Leaves ciliate, ſlightly waved, channelled at the baſe. Scape ſhorter than the leaves. Flowers blue or violet, very numerous, cluſtered, in a very large convex corymb. Bractes membranaceous, long, lanceolate, acute. Petals elliptic, ſubacute, ſpreading out horizontally. Stamens of the ſame colour, ſhorter than the corolla [b].]

There are two varieties of this, one with a deep blue, and the other with a white flower. It has been long known in the Engliſh gardens by the name of Hyacinth of Peru. [How it came by that name I know not, but it is a native of Spain, Portugal and Barbary. Parkinſon calls it, the great Spaniſh Starry Jacinth, and adds a bluſh-coloured variety. According to him, it is found in the meadows near Cadiz, and in going thence to Porto Santa Maria, ſo thick together, as to cover the ground, when in flower, like a tapeſtry of divers colours; as he was informed by Guillaume Boel, a Freeze-lander, who being in ſearch of rare plants in Spain, in 1607, after that moſt violent froſty winter, which periſhed both the roots of this, and many other fine plants with us, ſent Parkinſon over ſome of theſe roots for his garden, which he gathered in the places named, with his own hands.

6. Scape erect, ſimple, ſmooth, a palm high. Bractes on the ſcape and below the flowers alternate, membranaceous, lanceolate, upright and preſſed cloſe, ſhorter than the interſtices. Flowers ſubumbelled, on pedicels about a quarter of an inch in length. Corolla ſpreading, white-purple. Petals oblong, blunt. Filaments a little ſhorter than the corolla. Anthers oblong, blueiſh. Style a little longer than the corolla. Stigma capitate, lobed.—Native of Japan [c].]

7. Root large, ſolid, purpliſh, from which come out five or ſix leaves, lying on the ground, above a foot long, and an inch broad, keeled, channelled, and of a lucid green; from among theſe ariſe two, three or four purpliſh ſtalks, eight or nine inches high, ſuſtaining towards the top five or ſix flowers, which come out ſingly from the ſide; they are of a violet-blue colour, and appear in april. The ſeeds ripen in june.

[y] Retzius. [z] Hort. kew. [a] Linn. ſuppl. [b] Deſfontaines. [c] Thunberg.

[When the plant is in flower, the ſtems are altogether upright, but as the ſeed-veſſels advance in ſize and weight, they bend down. The ſeeds are of a pale amber colour, and drop ſoon. The germ in the flower is diſtinguiſhed for the paleneſs of its colour [d]. Linneus calls it yellow, and ſays that there are two whitiſh lines at the baſe of the petals.

Native of the Levant. Introduced by Edward Lord Zouch about the year 1600 [e]. Cluſius ſays it came from Conſtantinople, and was ſent to him at Frankfort, with other plants, in the year 1590, by a lady of the name of Ungnadin.

8. This is diſtinguiſhable at firſt ſight from the preceding by its habit, ſmallneſs, and earlineſs of flowering: but it differs farther in the length of the peduncles, the lower ones being three times as long and more, the upper ones twice as long as the flower: the bractes are blunt and ſo very ſmall as to be hardly viſible: the corolla is bell-ſhaped and one third only of the ſize: the leaves linear never bluntiſh, as in the preceding, attenuated at the baſe. The native country is not known [f].]

9. Bulb oblong, white; whence come out five or ſix leaves, a foot long, and half an inch broad, of a lucid green, and a little keeled. Scape nine or ten inches high, firm, and ſuſtaining many flowers at the top, diſpoſed in a looſe panicle, each on a pretty long pedicel which is erect, but the flower itſelf nods. Corolla of a deep blue violet colour.

Native of Spain and Portugal: flowering in may. [Cultivated in 1759 by Mr. Miller [g].

10. Bulb ſubovate. Leaves ſcarcely ever more than two in number, lanceolate, bluntiſh, ſomewhat keeled. Scape a little higher than the leaves, erect, round. Bractes either altogether wanting, or ſo minute as to be hardly perceptible. Corymb terminating, ſubracemed. Flowers from four to ten (Linneus ſays, often four, equal in height) on long pedicels, blue. Petals bluntiſh. Anthers browniſh [h].

Scape roundiſh. Peduncles all or moſtly on one ſide, the lower ones longer, tinged with red, round. Bractes wanting. Corolla as in the *italica*. Filaments blue. Anthers blueiſh with a dirty blackiſh pollen. Piſtil blue. Germ conical, ſix-grooved [i].

Native of Germany, Switzerland, Auſtria, France, Italy and England. It was cultivated in our gardens in the times of Gerarde and Parkinſon, and was not, till very lately, aſcertained to be a native of this country. Dr. Smith firſt introduced it into his Engliſh Botany, on the authority of Buddle's herbarium: but it has been ſince received from the weſt of England by Mr. Sims, druggiſt of Norwich [k]. It flowers in march and april.

β. It varies with a white flower: and having ſometimes three leaves, that is given alſo as a variety.

11. Bulb ovate, ſmall. Leaves many, linear, channelled, attenuated at the baſe. Scape round, erect. Corymb terminating, hemiſpherical. Flowers from three to ſix, ſeldom more, pedicelled, blue. Bractes the length of the pedicels, permanent, blunt. Petals ovate, keeled. Filaments round, with blue anthers. Germ roundiſh. Style ſhort. Stigma blunt [l].

According to Hudſon, the bulb is brown, the ſize of a hazel nut. Scape from two to ſix inches high. Leaves ſubulate-linear, acute, almoſt the length of the ſcape. Flowers from three to eight, and in gardens from ſix to ſixteen, pale blue. Bractes membranaceous, concave, acute, almoſt the length of the peduncle. Withering ſays, they are longer than the peduncle; that the flowers are from four to ſix; and that in a wild ſtate, the root-leaves are ſeldom more than two. Lightfoot alſo attributes only two or three leaves to it; and from two to ten flowers, on a ſcape about four inches high.

Native of Great Britain; and of Spain; if it be the *Ornithogalum hiſpanicum minus* of Cluſius. But Dr. Smith thinks that the ſynonyms quoted by Hudſon belong rather to *δ. italica*. Mr. Hudſon firſt

[d] Curtis. [e] Hort. kew. [f] Willdenow. [g] Hort. kew. [h] Smith brit. [i] Retzius. [k] Smith brit. [l] Idem.

Digitized by Google

proved this to be distinct from the Linnean *Scilla bifolia*, with which it had been confounded even by Ray himself.

I. verna is a maritime plant found among rocks in Cornwall, the western coast of Wales, the Isle of Man, and the Hebrides[m]. Mr. Heaton found it in Barge-island, North Wales, and at King's-end near Dublin; Mr. Willoughby, in Anglesey; Ray, in Bardsey-island abundantly, and in other islands and cliffs on the coast of Wales; Hudson, about St. Ives and elsewhere in Cornwall; Mrs. Watt, near Redruth, and Dr. Withering, near Penzance, in Cornwall, and Gloddaeth in Caernarvonshire; Mr. Hall, on cliffs in the Isle of Man; and Lightfoot, in the islands of Jona and Staffa abundantly. It flowers in april.

12. This resembles *Sc. amoena.* Scape round. Flowers distant, commonly shorter than the pedicel: petals elliptic, bluntish, marked with grooves and lines, spreading. Stamens a little shorter than the petals, with yellow anthers[o].

Native of Portugal. Introduced in 1777, by Edward Whitaker Gray, M. D. It flowers in may[p].

13. Root-leaves many, attenuated below, smooth, a span long. Scape erect, smooth, two feet high, with alternate spathaceous scales.—Native of Japan, in the island Niphon[q].

14. Flowers numerous, small, blue. Pedicels scattered, filiform, blue, three times as long as the flowers[r].

The offsets from the principal bulb are very numerous and bigger than the first. Scape three feet high, flowering almost from the middle to the top. Leaves flat, more than half a foot long, and an inch wide. Pedicels in threes or fours, so close as almost to seem in whorls, and an inch long. Corollas very small. Germ whitish. Bractes scarcely visible, solitary, and removed a small space from the pedicel[s].

Native of the Island of Madeira. Introduced by Masson in 1778. It flowers in august[t].

Gouan relates that it had been cultivated about a century in the botanic garden at Montpellier, and many other gardens thereabouts, when he first observed it flowering (in may) in the year 1767; when he sent it to Linneus, who reduced it to its proper genus.

15. Bulb ovate, coated, solid. Leaves five to seven, smooth, acute, flat, involved in a membranaceous sheath at the base. Scape slender, erect. Raceme short, ovate. Flowers on filiform pedicels, equal to the flowers. Bractes awl-shaped, membranaceous, scarcely longer than the pedicel. Corolla blue, of the same size as in S. italica; segments elliptic, obtuse. Filaments wide at bottom. Germ roundish.—Native of Barbary, in fields; flowering in winter.

16. Bulb ovate, solid, coated. Leaves spreading in a ring, unequal, obtuse or acute. Scape erect. Pedicels filiform. Bractes lanceolate, acute, concave, membranaceous, now shorter, now longer than the pedicels. Corolla blue, the same size as in Sc. amoena: the segments elliptic, bluntish. Stamens shorter than the corolla. Filaments flatted, wider below. Germ roundish.

Native of Barbary, in sands near Kerwan, flowering in winter.

17. Bulb ovate, solid. Leaves blunt, sometimes mucronate. Scapes often two, slender, round, simple, erect. Flowers like those of Sc. autumnalis, on filiform pedicels three times as long as the flowers. Corolla violet, with the segments elliptic. Stamens the length of the corolla. Capsule small, short, bluntly three-cornered. Seeds oblong, black.—Native of Barbary near la Calle.

18. Bulb ovate, solid, with the outer coat brown and membranaceous. Leaves four to six, unequal, thickish, very finely striated. Scape slender, erect, often twice as long as the leaves, quite simple. Flowers like those of Sc. autumnalis, on filiform pedicels twice or thrice the length of the flower spreading out horizontally. Raceme at first conical, then cylindrical. Corolla violet, with the segments elliptic and blunt. Stamens length of the corolla, with the filaments wider at bottom. Anthers blueish.

Native of Barbary, in fields about Algiers; flowering in winter.

19. Bulb ovate, compact, with the outer coats membranaceous and separating. Leaves spreading in a ring. Scape slender, simple, erect. Flowers on filiform pedicels. Bractes awl-shaped, very small. Corolla bell-shaped, spreading, pale rose-coloured; with the segments linear, bluntish, more deeply coloured in the middle. Stamens a little shorter than the corolla. Filaments slender equal. Style length of the stamens. Capsule blunt, triangular, pressed close to the scape. Seeds black, angular. The leaves come out after the flowering is over.

Very common in Barbary, on barren hills about Tunis, Constantine, Algiers, &c. flowering in autumn and at the beginning of winter[u].

20. Bulb ovate-roundish, coated, whitish. Leaves numerous, much shorter than the scape, two or three inches long, linear, obtuse, channelled, spreading. Scape from three or four to six inches in height, round, upright, striated, below whitish green, above purplish, appearing villose when magnified. Sometimes there is a second scape. Flowers six, ten or even twenty in a corymb, which is soon lengthened out into a raceme. Pedicels short, always pointing upwards, and after flowering pressed close to the scape, entirely destitute of bractes. Petals variegated with blue and purple: germ and stamens blue. The petals are callous and of a greenish-brown colour at the tips, three of them a little narrower than the other three. Anthers heart-shaped, large, at first deep purple, but blackish on shedding the pollen. Germ marked with six impressed white lines: style three-cornered, three-grooved, length of the stamens. Capsule roundish, having in each of the three cells two seeds, which are large, blackish, shining, three-cornered, the outer side convex, the two inner ones flat[x].

Native of France, Spain, Italy, Barbary and England.

The autumnal Squill, or Starry Hyacinth, as our old writers call it, is not very uncommon in dry pastures, in the southern and western parts of England. Gerarde was not aware of its being a native. Parkinson (in 1629) informs us, "that it is wild in many "places of England, and that he gathered it from "the foot of a high bank by the Thames side, at the "hither end of Chelsey, before you come at the "King's Barge-house." It occurs still in several places near London; as on Blackheath, where Plukenet observed it; near Ditton, on Moulsey-hurst, over against Hampton-Court, &c. where it was found by Merret; not many years since it was observed sparingly on Kew-green. Ray remarked it abundantly on St. Vincent's rocks near Bristol, and on the Lizard point in Cornwall. It is still found in those places; and according to Mr. Watt, it is common near Chace Water Mine in Cornwall[y].

It grows among grass, in a light and not very fertile loam, and is seldom above three inches in height. In a garden it is double the size, and produces several stems. It begins to flower about the third week in august, and continues three weeks or a month. In a wild state the flowering-stalks mostly come up without the leaves, in some few plants the leaves accompany them, and appear the greatest part of the year; but being small and grassy, they do not readily lead to a discovery of the plant.

Most old writers distinguish a larger and a smaller sort; but these differ merely in size. Parkinson notices a variety with white flowers[z].

21. Bulb ovate, coated. Flowers loosely racemed, on filiform pedicels a little shorter than the corolla. Bractes narrow, equal to the pedicels or shorter. Corolla nearly the size of *Ornithogalum pyrenaicum*, with elliptic, blunt, pale yellow segments.

Native

Digitized by Google

Native of Barbary near La Calle; flowering in autumn and winter [a].

22. Native of Portugal.

Dr. Smith has very properly removed Hyacinthus non-ſcriptus into this genus under the name of *Scilla nutans*. But it has already been deſcribed under the former name.]

PROPAGATION AND CULTURE.

1. The Officinal Squill growing on ſea-ſhores, and in ditches where the ſalt water flows in with the tide, in the warm parts of Europe, cannot be propagated in gardens, the froſt in winter always deſtroying the roots, and for want of ſalt water they do not thrive in ſummer. Sometimes the roots put out ſtems and produce flowers as they lie in the druggiſt's ſhops.

2, &c. The other ſpecies are moſtly hardy, and may be propagated by ſeeds or offsets: the latter, being the more expeditious way, is generally practiſed. The roots may be tranſplanted after the leaves are decayed; but if they are removed after they have put out new fibres, they rarely ſucceed, at leaſt they will not flower the following ſpring. They may be treated in every reſpect like the ordinary ſorts of Hyacinths.

The ſeeds ſhould be ſown in autumn ſoon after they are ripe, either in ſhallow boxes or pans in the manner before directed for Hyacinths.

[14. Dodonæus remarks, that unleſs the offsets are frequently taken from this ſpecies, it will not flower for twenty years together.

20. This may be raiſed from ſeeds, which it produces in plenty, and it will flower the third year. It may be increaſed alſo, though ſlowly, by its bulbs, which ſhould be planted in a light loamy ſoil, and placed in a dry part of the garden. It is beſt to plant the bulbs in pots, plunged in the border; for they will thus be ſecured from deſtruction, when the border is dug. This hint is applicable to any other ſmall hardy bulbs [b].

Leſſer Bull-ruſh.

γ. J. aquaticus medius, caule carinato. *Raii ſyn.* 428.

Culm round naked, panicle cymed decompounded terminating, ſpikelets ovate.

19. Scirpus glomeratus.
Lin. ſpec. ed. Willd. 1. 296. *Retz. obſ.* 4. 11. *n.* 19.

Culm naked roundiſh, umbel glomerate, involucre two-leaved ſhort, flowers two-ſtamened.

20. Scirpus arvenſis.
Lin. ſpec. ed. Willd. 1. 296. *Retz. obſ.* 4. 11. *n.* 20.

Culms compreſſed ſtriated, umbels ſimple, involucre one-leafed ſhort.

21. Scirpus truncatus.
Lin. ſpec. ed. Willd. 1. 296. *Thunb. prodr.* 17.

Culm round, head glomerate-globular, involucre two-leaved, leaves linear.

22. Scirpus laciniatus.
Lin. ſpec. ed. Willd. 1. 296. *Thunb. prodr.* 17.

Culm round, head triangular, glumes ovate ciliate, involucre two-leaved.

23. Scirpus membranaceus.
Lin. ſpec. ed. Willd. 1. 297. *Thunb. prodr.* 17.

Culm round, head angular, glumes ovate membranaceous, involucre three-leaved.

24. Scirpus piloſus.
Lin. ſpec. ed. Willd. 1. 297. *Thunb. prodr.* 18.

Culm compreſſed, head ovate, glumes lanceolate ciliate, involucre four-leaved.

25. Scirpus Hyſtrix.
Lin. ſpec. ed. Willd. 1. 297. *Thunb. prodr.* 17.

Culm capillary, head commonly two-ſpiked, glumes acuminate ſquarroſe, involucre one-leafed.

26. Scirpus Holoſchoenus. *Round cluſter-headed Club-ruſh.*
Lin. ſpec. 72. *ſyſt.* 99. *Reich.* 1. 133. *Willd.* 1. 297. *Hudſ. angl.* 19. *Wither. arr. ed.* 3. 75. *Smith brit.* 53. *Dickſ. hort. ficc.* 2. *Hoffm. germ.* 17. *Roth. germ.* 1. 22. 2. 58. *Scop. carn. n.* 61. *Sauv. monſp.* 8. *Villars dauph.* 2. 190. *Krock. ſilef. n.* 76. *Deſfont. atlant.* 49.

J. Lobelii. *Park. theat.* 1270. 10. & 9.
Gramen junceum minimum, capite ſquamoſo. *Bauh. pin.* 6. *prodr.* 13.
Culm naked ſetaceous, ſpikes lateral commonly two ſeſſile without braſtes.

30. Scirpus ſupinus.
Lin. ſpec. 73. *Reich.* 1. 134. *Willd.* 1. 299. *Roth. germ.* 2. 58. *Dalib. par.* 16. *Lour. cochinch.* 43. *ed. Willd.* 55.
S. ſupinus minimus, capitulis conglobatis, foliis rotundo-teretibus. *Tournef. inſt.* 528.
Culm round naked, ſpikes ſeſſile glomerate in the middle of the culm.

31. Scirpus natans.
Lin. ſpec. ed. Willd. 299. *Thunb. prodr.* 17.
Culm compreſſed leafy, flexuoſe-erect, ſpikes two lateral.

32. Scirpus vaginatus.
Lin. ſpec. ed. Willd. 1. 300. *Thunb. prodr.* 17.
Culm filiform, heads lateral alternate ſhorter than the involucre.

33. Scirpus triſtachyos.
Lin. ſyſt. 99. *Willd.* 1. 300. *ſuppl.* 103. *Thunb. prodr.* 17. *Rottb. gram.* 48. *t.* 13. *f.* 4.
Culm capillary, head three-ſpiked, glumes entire, involucre two-leaved.

34. Scirpus uncinatus.
Lin. ſpec. ed. Willd. 1. 300. *Pluk. phyt. t.* 190. *f.* 7.
S. capitatus. *Burm. ind.* 21 ?
Hairy, culm round leafy, ſpikes conglomerated into a head terminating and axillary.

35. Scirpus ariſtatus.
Lin. ſpec. ed. Willd. 1. 300.
S. piloſus. *Retz. obſ.* 6. 19. *n.* 12.
Culm ſtriated round leafy, panicle terminating two-leaved, ſpikelets oviate ſquarroſe-echinate.

36. Scirpus autumnalis.
Lin. ſyſt. 99. *Reich.* 1. 134. *Willd.* 1. 301. *mant.* 180. *Rottb. gram.* 58. *t.* 17. *f.* 3? *Clayt.* 772.
Culm ancipital naked, umbel decompounded, ſpikelets oviate.

37. Scirpus diphyllus.
Lin. ſpec. ed. Willd. 1. 301. *Retz. obſ.* 5. 15. *n.* 22.
Culms ſemicylindrical ſtriated two-leaved, umbel compound with a two-leaved involucre longer than it.

38. Scirpus faſtigiatus.
Lin. ſpec. ed. Willd. 1. 301. *Thunb. prodr.* 18.
Culm filiform, head convex compreſſed, outer glumes mucronate, involucre none.

39. Scirpus globuloſus.
Lin. ſpec. ed. Willd. 1. 301. *Retz. obſ.* 6. 19. *n.* 11.
Culm compreſſed naked, panicle terminating, ſpikelet ſingle ſeſſile, ſeveral peduncled globular.

40. Scirpus globiferus.
Lin. ſyſt. 99. *Willd.* 1. 301. *ſuppl.* 104.
Culm naked round, umbel terminating compound, heads globular compoſed of ſeveral ſpikelets cloſely heaped.

41. Scirpus capillaris.
Lin. ſyſt. 99. *Reich.* 1. 135. *Willd.* 1. 302. *mant.* 321. *fl. zeyl. n.* 39. *hort. cliff.* 21. (Cyperus.) *Burm. zeyl.* 109. *t.* 47. *f.* 2. (Gramen puſillum.)
Culm naked capillary, ſpikes peduncled in threes, the middle one ſeſſile.

**** Culm three-ſided, panicle naked.*

42. Scirpus triſpicatus.
Lin. ſyſt. 99. *Willd.* 1. 302. *ſuppl.* 10. *Thunb. prodr.* 17.
Culm angular naked, ſpikes terminating in threes ſeſſile naked.

43. Scirpus lateralis.
Lin. ſpec. ed. Willd. 1. 302. *Retz. obſ.* 4. 12. *n.* 24. & 5. 16. *n.* 25.
Culms three-ſided naked, ſpikes ſubtern lateral, involucre one-leaſed ſhort.

44. Scirpus triqueter. *Triangular Club-ruſh* or *Bull-ruſh.*
Lin. ſyſt. 99. *Reich.* 1. 135. *Willd.* 1. 302. *mant.* 29. *Roth. germ.* 1. 23. 2. 59. *Smith brit.* 55. *Withet. arr. ed.* 3. 70. *Mich. gen.* 47. (Scirpo-Cyperus.)

Culm three-sided naked, head ovate squarrose, involucre three-leaved long.

DESCRIPTIONS, *&c.*

1. This resembles S. geniculatus very much, but the culm is three-sided, softish and not jointed [c]:—almost hollow, and partitioned by frequent transverse septa. It is frequent in all the shallow standing waters of Jamaica, especially those to the east and west of Kingston [d].

2. Native of the East Indies.

3. Culm hollow, jointed but not all round. Spikes lateral collected into a half-whorled head [e].

Root in bundles, fibrous, eatable. Culms several broken by joints at an inch distance, striated, smooth. Between the joints the streaks approximate and become indistinct [f].—Native of Malabar, Egypt and Japan.

4. Culms three or four feet high, sheathed at the base, striated, jointed with very frequent transverse septa between the joints, appearing on the outside, at least in the dry specimen. Leaves shorter and compressed towards the end. Spike an inch long, closely imbricate.—Native of the East Indies [g].

5. Root fibrous. Culms several, a span high, filiform, compressed, in a manner four-cornered by a deeper streak on the narrower sides, having short brown scales at the base, and one or two leafless sheaths an inch in length. Spike naked, with ovate, entire, scarious browniſh scales.—Native of Malacca [h].

6. Root creeping horizontally, throwing out many yellowish fibres, and producing thick tufts of upright, cylindrical, smooth, naked stems, becoming striated when dry, clothed at their base with a close blunt sheath, which is invested with two or three other shorter more membranous and reddish sheaths. It has no leaves, unless the barren culms or stems be taken for them. Spikes solitary at the end of each stem, erect, naked, many-flowered, oblong, appearing oval from the spreading of the scales in flowering, and sometimes accompanied by a small, membranous, close-pressed bracte. Scales brown, acute, with a white scarious edge. Anthers large, yellow, projecting entirely beyond the scales. Seed roundish, smooth, yellow, with a brown apex; having four bristles at the base, according to Leers: who says also that the flowers have always two anthers, never three.

It varies in height from six inches to two feet or more: hence some authors make two varieties of it.

[c] Linn. spec. [d] Browne. [e] Linn. spec. [f] Thunberg. [g] Retz. [h] Idem.

Native of Europe, Asia and Africa. Very common in England, in ditches, ponds, marshes and rivulets; flowering in june and july.

Swine devour the roots greedily when fresh, but will not touch them when dry [i].

7. Root putting out long thicker fibres, but not creeping. Culms numerous, in tufts, spreading loosely, a span high, cylindrical, smooth, striated chiefly at the base and closely sheathed separately, with cylindrical, stiff, truncate, entire, subacuminate sheaths, generally doubled, but without any scales between. Leaves none. Spike ovate or elliptic, ferruginous, naked, many-flowered. All the scales are equal, imbricate, ovate, blunt, dark-purple or brown, somewhat scarious at the top, with an indistinct green keel. One or two of the floscules at the base of the spike frequently become viviparous and divaricate.

Native of Lapland, where it was observed by Rudbeck, and considered by Linneus as a variety of the preceding: also of Denmark. Mr. John Mackay, discovered it in 1794, on a bog near the house of Mr. M'Kinnon, at Corrybattachan, in the Isle of Skye [k].

8. Culms five or six, from two to three feet high, of a fine shining green colour, hollow, with many transverse membranes. Head oblong, scaly, white. It varies in size, and is found in holes of the low lands where water has stood, in Jamaica [l]. Browne says it is very like the common Bull-rush.

9. Root fibrous, tufted. Culms numerous, upright, varying much in height (according to Dr. Stokes, from two to six inches,) equal, smooth, striated, sheathed at the base, with one or two loose leafy striated entire sheaths, having the top oblique, ending in a short blunt point, and fenced with numerous membranaceous whitish-brown striated concave imbricately sheathing scales, smaller outwards and permanent. Spike small, rufous. The two outer glumes (a little unequal) are the length of the whole spike, and have a leafy point [m]. Dr. Stokes remarks that the seeds have hairs at the base. Dr. Withering observes, that the length of the spike and of its lower scales is extremely uncertain: sometimes these lower scales are as long as the spike, sometimes not half so long, and in other instances considerably longer, the point of the outer valve being lengthened into a kind of awn. This species is therefore best distinguished from the *palustris* by the green and leaf-like appearance of the upper sheaths at the bottom of the culm.

Native of Europe, in bogs, flowering in july. The principal food of sheep and cattle in the highlands of Scoland in march and april till the end of may [n].

10. Root tufted, blackish. Culms almost upright, from three to six inches high, slender, smooth, having a stiff, awnless, equal sheath at the base. Root-leaves (or rather barren culms) similar and often higher, sheathed in the same manner at the base. Spike small, reddish brown, having about four flowers, with the two lower glumes almost equal, elliptic, shorter than the spike and awnless.

It is very distinct from the preceding, with which it has been confounded by Linneus and Hudson, by the almost total want of the radical scales; by the sheaths being strict, blunt and awnless; the lower glumes shorter than the spike; and by having radical leaves (or barren culms [o].)

Mr. Woodward remarks, that this is very different in habit from the *cæspitosus*; that besides its growing single and not in tufts, the stems generally decline and scatter from each other, instead of being upright and close together; that the stems are also more rigid, of shorter growth, and the flowers fewer.

Native of Sweden, Germany, Switzerland, France and Britain. Found in Ellingham fen, Norfolk, by Mr. Woodward; plentifully on Poringland heath, near Norwich, by Mr. Crowe; Houghton-moor, near Newbold, and near Beverley, Yorkshire, by Mr. Teesdale; and on the highlands of Scotland, by Mr. Stuart: flowering in auguſt.

[i] Smith brit. and engl. bot. Withering. [k] Smith brit. [l] Sloane. [m] Smith. [n] Lightfoot. [o] Smith.

11. Native

11. Native of the Dutchies of Oldenburgh and Bremen.

12. Native of Virginia and the Caribee iſlands.

13. This differs from *acicularis* in habit, in having much larger ovate heads of a bay colour, and a longer culm which is yellow not green. The pale-yellow colour of the plant diſtinguiſhes it at firſt ſight from *paluſtris*; the tufts are alſo much thicker, and the culms have ſcarcely any pith [y].—Native of Germany and Sileſia.

14. This reſembles *Sc. capitatus*, (n. 12.) but is more ſlender. Culms cluſtered, ſtrict, roundiſh, ſtriated, naked, having a ſhort purpliſh ſheath at the baſe; from an inch to half a foot in height. Leaves ſimilar, few. Spike naked, dark purple, eſpecially in the rainy ſeaſon. Scales ovate, blunt, with a green keel. Seed dark, with a few ſnow-white briſtles at the baſe. Native of the Eaſt Indies, in boggy grounds: found by Koenig.

15. Culms in tufts, depreſſed, from four to ſix inches high, ſtriated, ſheathed together with the leaves at the baſe. Leaves ſhorter, filiform. Spike ſubovate. Bracte ſomewhat ſhorter than the ſpike, acuminate. Scales ovate, keeled, blunt, ſcarioſe, brown at the tip. Stamen one, ſeldom two.

Very common in low wet paſtures in Ceylon [q]. Alſo in Amboyna.

16. Root fibrous, tufted. Stems numerous, from two to four inches high, very ſlender, erect, roundiſh when freſh, but marked with four ſmooth angles, which in drying become very conſpicuous: the baſe is inveſted with a tight blunt beardleſs ſheath. Leaves few, ſhorter than the ſtems, obſoletely quadrangular, being flat above, and ſomewhat rounded beneath. Spike ſmall, ſolitary, compoſed of five or ſix flowers, the glumes of which are truely imbricate in every direction, not two-ranked; ſo that it properly belongs to this genus, and by no means agrees in character or habit with Cyperus. Each glume is ſharply keeled and pointed, with a membranous margin; the two lowermoſt are rather larger, and ſometimes barren. Seed elliptical, without any briſtles at the baſe.—All authors, except Hudſon, have deſcribed the culm as round, which is a miſtake. This ſmall plant grows in damp places, where water has ſtagnated in winter, on heaths and commons: flowering in auguſt [r]. In England, it has been obſerved on Hounſlow-heath, towards Hampton, by Mr. Doody; on Epping Foreſt, near Wanſtead, and in Wanſtead-park, Eſſex, by Mr. Edward Forſter, jun.; on Malvern-chace, in Worceſterſhire, by Mr. Stokes; on Binſey-common, by Dodſworth, and near Eynſham-bridge, in Oxfordſhire, by Sibthorp; in Dorſetſhire, by Pulteney, who remarks that it was firſt noticed by Plot; as *cæſpitoſus* ſeems to have been, in England, by Merret, and *fluitans*, by Ray: on Stockton Common, Terrington Car, and other watery heaths in Yorkſhire, by Mr. Teeſdale.

17. Root ſmall fibrous; the ſtems alſo throw out many long fibres from the joints as they float many together on the ſurface of the water. Stems round, ſtriated, branched, very long, moſt ſlender at the baſe, with the internodes there lengthened out; towards the top thickened a little, with the joints nearer. Leaves linear, ſheathing at the baſe, flaccid, floating, in alternate ſingle bundles at the joints. Peduncles axillary towards the upper part of the ſtem, ſolitary, round, ſtriated, ſtraight, two inches long. Spikes erect above the ſurface, and though ſmall conſpicuous by their number and whitiſh colour. Their form is ovate, and each conſiſts of few flowers, the glumes of which are not much ſhorter than the ſtamens; the two lower or outer are mucronate and particularly large, ſo as to appear like bractes, but they have always parts of fructification belonging to them. The ſtigmas are only two in number.

Native of Germany, France, Flanders and England, in ditches and little pools upon graſſy commons and heaths, where the water is apt to be dried up in ſummer; in which caſe it ſometimes grows more luxuriantly [s].

Mr. Doody gathered it on Wandſworth-common, and in the ſame place with the Pepper-graſs [t], that is on Streatham-common in Surry. Mr. Blackſtone, in the bogs on Harefield-common. Mr. Hudſon, on Putney and Hounſlow heaths. Mr. Crowe and Mr. Dickſon, on the heath between Farnham and Godalmin. Dr. Smith, on St. Faith's bogs near Norwich [u]. Dr. Pulteney, on Chorley-foreſt in Leiceſterſhire, and in Dorſetſhire abundantly. Mr. Hall, in ſmall rills about Newton Cartmell. Mr. Robſon, at Saleſmoor near Mancheſter [x]. Mr. Teeſdale, upon Stockton-common, Terrington Car, and many other watery heaths in Yorkſhire; with the cæſpitoſus, acicularis and ſetaceus [y]. By Morton, at Badby in Northamptonſhire. By Ray, at Madern near Haverford-Weſt in Pembrokeſhire [z].

18. Roots creeping under water horizontally, thick and ſtrong. Stems ſtraight, four or five feet or much more in height, naked, round, ſmooth, dark green, very ſpongy and full of watery juice within, with ſeveral alternate ſheathing ſcales at the baſe. Panicle decompounded in a cyme-like form: its branches are very unequal, compreſſed, and fringed towards their extremities. Bractes two exterior, lanceolate, acute, ſheathing, commonly ſhorter than the panicle; and many interior ones which are ſmaller. Spikes cluſtered, (generally two or three together) ovate, brown with a ſhining ruſty tinge. Glumes concave, keeled, pointed, fringed, ſometimes cloven, but with a ſerrated point in the cleft. Stamens not very long. Stigma three-cleft. Seed flat on one ſide, convex on the other, with five or ſix ſhort rough briſtles at its baſe.

It varies in the length of the bractes, and height of the culm: in β the panicle is ſmaller; and in γ the culm, according to the obſervation is flatted on one ſide.

Native of Europe, Siberia, Japan and Jamaica; growing abundantly in clear ditches and ſtreams, fens, pools and lakes; flowering in july and auguſt [a].

Bottoms of chairs are very commonly made of the Bull-ruſh: if cut at one year old, it makes the fine bottoms; coarſe bottoms are made of it at two years old; ſuch as are ſtill older, mixed with the leaves of Flag, (Iris Pſeudacorus) make the coarſeſt bottoms. Mats are likewiſe made either of this alone, or mixed with Flag leaves. Cottages are ſometimes thatched, and pack-ſaddles ſtuffed with it [b]. It is of a ſoft pliant texture, totally deſtitute of the roughneſs or cutting edges of many graſs-like plants. In hard ſeaſons cattle will eat it [c].

19. Roots long, filiform. Leaves radical, cluſtered, ſhort, rigid, curved. Culm grooved, naked, ſolitary, a palm high. Umbel compound. The two leaves of the involucre are ſtiffiſh and ſhorter than the umbel; beſides theſe there are a few ſcarioſe ſcales. Spikelets ovate. Scales wide, blunt, concave, brown edged with white.—Native of Ceylon. Found by Koenig.

20. Culms two feet high, clothed at the baſe by a brown angular ſheath two inches in length. A ſhort leaf iſſues from the ſheath with the culm. The umbel is compoſed of from five to eight ſpikes; and ſometimes, but ſeldom, an intermediate peduncle bears two pedicelled ſpikes. The involucre is moſtly one-leafed and ſhorter than the umbel. Spikes ovate, brown, peduncled; with lanceolate ſcales, gradually deciduous from the baſe.—Koenig ſent it from Ceylon [d].

21. 22. 23. 24. 25. All natives of the Cape of Good Hope, where they were found by Thunberg [e].

26. Root tufted. Culms almoſt upright, two or three feet high, ſmooth, very finely ſtriated, ſheathed at the baſe with a torn membrane. Leaves radical, linear, acute, pungent, ſmooth, not keeled but channelled above with a white hollow. Heads ſeſſile or on angular peduncles ſheathed at the baſe ſometimes branched, brown, compoſed of numerous blunt ſpikelets, with concave acute ſtriated ſcales between, pu-

Digitized by Google

beſcent at the edge. Bractes two unequal, quite ſimilar to the leaves, the upper one ſeeming to be a continuation of the culm, varying much in length from two inches to a foot, from ſtraight curved in; the lower much ſhorter, more or leſs divaricating. The ſtructure of the flower is ſcarcely known. The ſeeds, according to Scheuchzer, ſeem to be beardleſs; ſtigma trifid. The upper involucre, as alſo the lower, being channelled with a white hollow line, and mucronate-pungent, like the leaves, ſhews that the fructification is truly terminating in this as in *lacuſtris*.

Dr. Smith has joined this with *auſtralis* and *romanus* as one ſpecies, on a compariſon of the ſpecimens of Linneus, Jacquin, Seguier and others, and on the admonition of Linneus himſelf in his later manuſcripts.

In α and γ the culm is more ſlender, the heads fewer and ſomewhat larger. Linneus had not ſeen the leaves of *S. romanus* when he deſcribed *S. auſtralis* in Syſtema Vegetabilium from the Hortus Upſalienſis[f].

Native of England, Germany, the ſouthern parts of Europe and Barbary.—Found by Mr. Stephens in Braunton Boroughs, Devonſhire; in Somerſetſhire and Hampſhire[g]; the place of β is unknown, Dr. Smith has not found it:—γ occurs in the South of France, Auſtria, Siberia, about Rome, and in England in marſhes near Throgmorton in Worceſterſhire; found there by the Rev. Mr. Sheffield[h].

27. Native of the Cape of Good Hope.

28. Culm leafleſs, a palm high, roundiſh, ſtriated. Leaves linear, channelled, even, ſtiffiſh, a ſpan high. Head the ſize of a Plum. Involucre eight-leaved, length of the culm, lanceolate, three times as wide as the leaves, yellow. There are other leaflets among the heaps of flowers, like the involucre, but ſmaller. Flowers from ſmall lanceolate one-flowered ſcales, all from the baſe and not imbricate. Stamens three. Style one. Seeds without any beard.—Native of the Cape of Good Hope[i].

29. Root fibrous tufted. Culms numerous, two or three inches high, ſtriated, ſmooth. Leaves like the culms, but ſhorter, with a cylindrical ſtriated ſheath. Spikes commonly two, but often ſingle, ſometimes three or four, breaking out laterally a little below the top of the culm, without any bracte beneath, ovate, ſmooth; glumes nearly equal, brown, keeled with a green nerve and mucronate. Seeds, according to Leers, beardleſs[k]. Dr. Stokes alſo ſays that they are naked. Dr. Withering deſcribes the plant as from two to ſix inches high; and the ſpikes as greeniſh-brown with a roſy tinge.

According to Gærtner, the glumes are ſimple, convex, imbricate every way into ovate ſpikes, which are not compreſſed. He conſiders the fruit as a nut, which is very ſmall, roundiſh or obovate, cruſtaceous, brittle, convex on one ſide, flattiſh on the other, acuminate at top with the permanent ſtyle, contracted below into an umbilical tubercle, longitudinally grooved, of a cheſtnut-ruſſet colour. Seed obovate, lenticular, ruſſet-coloured, faſtened to the bottom of the nut.

Native of moſt parts of Europe, in wet ſandy ground, and on ſandy coaſts: flowering in july and auguſt.

The deſcription in Linneus's Mantiſſa (321) belongs to another ſpecies, native of Portugal and the Cape of Good Hope, which is perhaps *Cyperus minimus* of Linneus; united with this by Rottboel.—*Sc. ſupinus*, which the ſame author confounds with this, is certainly diſtinct from both[l].

30. Culms a foot and half high, ſtriated. Leaves awl-ſhaped, ſhort. Spikes ovate, three or four together. Seed turbinate, compreſſed, ſhort, ſurrounded by rough villoſe hairs ſhorter than the calyx[m].

Native of France near Paris, the March of Brandenburgh, and Cochinchina.

31. 32. Natives of the Cape of Good Hope.

33. Culms and leaves ſetaceous and very ſmooth. Head lateral, immediately below the top of the culm, compoſed of from three to ſeven ſpikes. It varies in ſize, and very much reſembles *S. capillaris*, but the ſpikes are not peduncled; perhaps it is only a variety of that. Native of the Cape of Good Hope[n].

34. Culm two inches high, hairy. Leaves graſſy, hairy on both ſides, wide in proportion to the plant. The terminating ball of flowers has a two-leaved ſhort hairy involucre; the other is peduncled and naked, in the axil of the uppermoſt leaf. Scales lanceolate, ſtraw-coloured, mucronate, uncinate, with a raiſed nerve.—Native of the Eaſt Indies[o].

35. Culm a ſpan high, ſlender, hairy towards the upper part. Leaves radical, and one in the middle of the culm, ſomewhat longer than it, one ſixth of an inch wide, nerved, hairy above and about the edge. Panicle ſhort, almoſt faſtigiate; peduncles one or two-ſpiked and very hairy. Involucre two-leaved: lower leaf five times as long, upper as long and half as the panicle, of the ſame form with the leaf, and hairy even beneath. Spikelets one ſixth of an inch in length, with abundance of whitiſh hairs on them. Scales imbricate, obovate, thin, pellucid, ſtriated, terminated by a white thread like an awn the length of the ſcale itſelf, and pinnate as it were with ſtraight white hairs on each ſide. Stamens three brown the length of the ſcale. Germ three-ſided, brown. Style length of the ſtamens. Stigmas three.

Native of the Eaſt Indies[p]. Willdenow has changed Retzius's trivial name; another ſpecies having been named *piloſus* by Thunberg.

36. This has the appearance of *Juncus piloſus*. Leaves radical, graſſy, looſe, ſomewhat rugged, often the length of the culm. Culms a hand high, compreſſed, keeled a little on one ſide. Involucre terminating, two-leaved, like the leaves, commonly longer than the umbel; which is ſpreading and unequal. The peduncles have generally three ſpikes. Scales ovate, ferruginous with a green keel, ſcarcely mucronate[q].

Rottboell's plant appears to be different from this[r].

Native of Virginia and Jamaica.

37. Culms two or three feet high, filiform. Leaves glaucous; thoſe next the root ſhorter, thoſe on the ſtem almoſt the length of the culm, graſſy. Umbel unequal. The two leaves of the involucre like the radical leaves, and beſides theſe one or two filiform and ſhorter. Involucrets ſhort, ſcarioſe. Spikelets ovate, pedicelled. Scales ovate, acute, concave, brown, with a green line on the back. Filaments flat. Germ obovate, acute, compreſſed, convex on both ſides, ſtriated longitudinally, very minutely wrinkled tranſverſely. Style widiſh, compreſſed, longitudinally haired on each ſide. Stigma bifid.—Koenig ſent it from Tranquebar[s].

38. Native of the Cape of Good Hope.

39. Culms a ſpan high, the thickneſs of a coarſe thread. Peduncles undivided one-ſpiked, ſeldom bearing a ſecond ſeſſile ſpike, from two to eight lines in length, unequal, clothed with a very ſhort ſheath at the baſe: theſe ſheaths are terminated by a very ſhort leaf, or rather the top is free or looſe. Scales roundiſh, very blunt, concave, brown with a whitiſh margin. Stamens three. Style one. Stigmas three, hirſute, brown.—Native of the Eaſt Indies[t].

40. Culm very ſmooth, terminated by a very ſhort two-leaved ſpathe; the leaflets equal, awl-ſhaped, mucronate. Peduncles ſpringing from the ſpathe many, ancipital, terminated by little balls, compoſed of very ſhort ſpikes cluſtered together. Theſe little balls put forth about the baſe, other rays bearing balls, which are again ſubdivided: hence the inflorescence reſembles a compound umbel with the umbels proliferous at the baſe.—Native of Teneriffe[u].

41. Leaves capillary, ſcarcely a finger's length. Culms ſcarcely longer or thicker than the leaves. Under the umbel is a ſetaceous leaflet longer than the ſpikes. Spikes terminating, ovate. Scales ferruginous with a green keel, blunt.—Native of Ceylon[x].

42. Leaves ſcarcely any except ferruginous radical

[f] Smith brit. [g] Ray ſyn. [h] Hudſon. [i] Linn. ſuppl. [k] Smith brit. [l] Idem and Reichard. [m] Loureiro. [n] Linn. ſuppl. [o] Willdenow. [p] Retzius. [q] Linn. mant. [r] Willdenow. [s] Retzius. [t] Idem. [u] Linn. ſuppl. [x] Linn. mant.

Digitized by Google

ſcales. Culms many from a foot to two feet in height, very ſmooth. Spikelets oblong, ſmall, equal, erect. Involucre many-leaved; the leaves awl-ſhaped, very ſhort.—Native of the Cape of Good Hope [y].

43. Culms from a ſpan to a foot in height, filiform, ſheathed at the baſe. Leaves of the ſame form, but ſhorter. Spikes from two to eight, ovate, of which one is on a peduncle a little above the middle of the culm. They generally have a ſhort, one-leafed involucre. Scales pale brown with a green keel, ovate, acute, concave. Stamens three, with linear anthers. Germen three-cornered, acute at both ends. Style ſhort, with the ſtigma ſlightly bifid.—Koenig gathered it in Ceylon [z].

44. Root fibrous, tufted, Culms erect, three feet high, flat at the ſides and even at the corners, ſpongy within, with a ſharp top a little bent in; (in variety β, which is maritime, firmer, according to Dillenius.) Spikes without bractes, having a few membranaceous ſcales between, on triangular peduncles, ſometimes branched and equalling the top of the culm. Glumes bay-coloured, ovate, keeled, mucronate, with a widened torn margin [a].

Native of Germany, England and ſome other parts of Europe; alſo of North America. With us it is found on the ſea ſhore, and on the banks of large rivers, as by the Thames, both above and below London. In ditches by the ſide of Acle dam, Norfolk, by Mr. Crowe. It was obſerved by Merret, and was firſt ſhowed to Mr. Ray by Doody. Ray had not ſeen it when he publiſhed his hiſtory of plants.

Sc. mucronatus of Linneus, not yet diſcovered in England, has the ſides of the culm not flat, but a little hollowed, with the point bent back; the glumes more numerous, ſtriated, green, with the margin ferruginous and entire, not widened and torn [b].

β. This variety was found in the iſland of Jerſey, by Sherard [c].

45. This is eaſily diſtinguiſhed from the preceding by its greater ſtature, its thicker culm with the ſides hollowed, its thicker ovate ſpikelets, twenty or more collected into a head, finally by the point or upper part of the culm not being upright but bent horizontally [d].

Native of Switzerland, the South of France, Carniola and Italy.

46. Koenig ſent two varieties from Ceylon: one two feet high, with a large, diffuſed and very branching umbel; the other half a foot high, with a ſmall umbel, ſparingly branched: both have naked compreſſed culms, with one ſide plane the other ſomewhat convex, and white ſeeds [e].

Vahl remarks, that Forſkahl's *biſumbellatus* from Arabia, recedes from Eaſt Indian ſpecimens only in ſize and villoſity; and this ſpecies is polymorphous.

It is an annual plant, which few of the Scirpi are. Allioni deſcribes his *annuus* as having the leaves even ſtriated linear and ſoft, the culm ſtriated, a little higher than the leaves, from three to ſix inches in height, many from the ſame root, involucre of two unequal leaves, the ſhorter ſcarcely equalling the peduncle, the longer ſometimes meaſuring the entire umbel, ſpikelets ovate-acuminate, one ſeſſile in the centre, the others on unequal three-ſided peduncles. The peduncles commonly bear one ſpike, but they are ſometimes prolliferous, and put forth another ſeſſile ſpikelet placed lower and alſo peduncled, having a leaflet at its baſe, but the ſpikes and peduncles are naked. Number of the peduncles in the umbel various, from two to ſeven. Glumes preſſed cloſe, acute, bay with a green nerve; but the lower ones and thoſe which embrace the ſpike at the baſe are awned, the nerve being produced into an awn. Seed elliptical, aſh-coloured, ſtriated.

According to Desfontaines, the leaves are pubeſcent, acute, ſoft, very ſlightly ſerrate; culm ſtriated, upright, a little higher than the leaves; involucre five-leaved or thereabouts, the leaflets unequal, ſome longer than the corymb. Peduncles many-ſpiked; the central ones very ſhort or none, the lateral ones ſuperdecompound, with the pedicels unequal and ſhort; the central ſpikelet ſeſſile. Spikelets ovate, ruſeſcent. Scales ovoid, mucronate, membranaceous at the edge, and having a raiſed dorſal line. Seed ſtriated. Number of the peduncles variable from two to eight.

Thus if the *annuus* of Allioni, the *biſumbellatus* of Forſkal, and the *dichotomus* of Linneus, be the ſame plant; it is a native of the Eaſt Indies, Arabia, Italy and Barbary.

47. Culm a ſpan high. Leaves carex-form, length of the culm. Spikes eight, each on its proper peduncle forming a ſort of umbel, compoſed of capſules which are acuminate and have no ſcales between them. Involucre of four or five long leaflets [f].—Native of both Indies.

48. Native of Virginia.

49. This ſpecies varies remarkably, from a ſpan to two feet in height. It is eaſily diſtinguiſhed by its unequal ciliate involucre.

Native of Jamaica and other iſlands of the Weſt Indies, both in dry and wet ſituations [g].

50. Culms two feet high, erect, ſlender, ſtriated, ſmooth, convex on one ſide, flattiſh on the other, with the angles rugged backwards. Leaves narrow, ſmooth, ſhorter than the culm. Umbel terminating compound: univerſal with eight or nine unequal rays, three or four inches long or leſs, convex on one ſide channelled on the other, ſmooth, rugged at the edge like the culms: partial with eight rays, an inch long or ſhorter. Univerſal involucre three or four-leaved; with a leaflet equal to the longer rays, the reſt an inch in length or leſs, rugged as before and channelled; the two oppoſite exterior ones larger, brown at the baſe: partial involucre two or three-leaved. Spikes three on each ray of the partial umbel, oblong, finally cylindrical, ſharpiſh, imbricate, brown and ſhining: the middle one ſeſſile. Scales oblong, blunt, convex, concave, keeled at the tip; the keel running out into an obſcure point.—Native of South America [h], Virginia, and Jamaica.

51. Culm about two feet high, even. Leaves at the baſe many, length of the culm, flat, three-nerved, naked, unarmed, half an inch wide: on the culm three like theſe but ſhorter. Panicle an inch and half long, with ſhort half-round ciliate-ſcabrous peduncles. The involucre conſiſts of a leaf under the loweſt peduncle four times as long as the panicle and ciliate-ſcabrous, another like this but ſcarcely longer than the panicle under the ſecond peduncle, and of ſeveral other leaves gradually ſhorter but all ciliate-ſcabrous. Peduncles from three to five-flowered. Pedicels very ſhort, with two or three lanceolate ſcales. Spikelets ovate, with imbricate ovate blunt ſcales. Lower flowers one-ſtamened, upper two-ſtamened. Corolla two-petalled, about the ſize of the calycine ſcale. Glumes equal, compreſſed, with the keel ciliate. Style length of the corolla. Stigmas two, ſhorter than the filaments, villoſe [i].

According to Vahl, his *Schoenus nemorum*, to which he refers Rheede's *Beera-Kaida*, (hort. malab. 12. 109. t. 58.) ſeems to agree with this, but he does not decide, Koenig's ſpecimens being imperfect in the fructification. On his authority, Vahl has made it a *Schoenus*.

Willdenow remarks, that reſpecting the genus it is yet doubtful; having a two-valved corolla. He ſuſpects that it may belong to the genus *Kyllingia*.

Native of the Eaſt Indies.

52. Culms very many, even, half a foot high. Leaves graſſy, clothing the baſe of the culm, even. Umbel looſe, diffuſed. Involucres general and partial leafy-ſetaceous, ſhorter than the umbel. Spikes peduncled except one which is ſeſſile in the ramifications of the umbel; all ovate, as ſmall as the ſeeds of Millet [k].

According to Retzius, the culms vary from half a foot to a foot and half in height. Leaves equitant at

[y] Linn. ſuppl. [z] Retzius. [a] Smith. [b] Idem. [c] Ray ſyn. [d] Willdenow. [e] Retzius. [f] Linn. zeyl. [g] Swartz obſ. [h] Vahl ecl. [i] Retzius. [k] Linn. ſpec.

Digitized by Google

the baſe.. Spikelets globular, by no means ovate. Stigmas two, bent.—Native of the Eaſt Indies.

53. Roots creeping, knotty at the extremities, ſometimes more evidently and conſtantly ſo than they are in general; hence variety β. Stems upright, from a foot to three feet in height, ſtriated, leafy, the angles roughiſh. Leaves linear, acute, very long, rugged at the edge, keeled, ſuddenly for the moſt part contracted to a ſharp point; the lower ones ſheathing and alternate, thoſe under the panicle ſeſſile and very unequal in length. Spikes terminating among the upper leaves, cheſtnut-coloured, glomerate, ſeſſile or peduncled, ovate; peduncles three-ſided, ſimple; ſometimes cylindrical and very long. Glumes ſhining, duſky ruſty-coloured, ovate, keeled, long-pointed, torn at the ſummit. Seeds triangular, flatteſt on one ſide, having moſtly one ſhort rough briſtle at the baſe, ſometimes more. So nearly are the genera of *Scirpus* and *Eriophorum* allied [l]!

There are many varieties of this ſpecies. The panicle is ſometimes branched, ſometimes ſimple. In ſome the ſpikes are ſeſſile, and the ſtem-leaves ſhorter than the culm; in others they are longer; and in ſome plants the ſpikes are ſome ſeſſile, others peduncled, as deſcribed above [m].

Desfontaines gives the knobby-rooted variety as a diſtinct ſpecies, under the name of *tuberoſus*. He adds the ſynonyms of Caſpar Bauhin, in our variety α; of Moriſon, in our variety γ; and of Scheuchzer, in our variety δ.—He doubts whether it be a diſtinct ſpecies from the *maritimus* of Linneus; but ſays that it differs not only in having roots with round knobs, but ſpikelets fewer in number, cluſtered, narrower, ſeſſile or on ſhort peduncles. He found it in lakes near La Calle in Barbary.

Linneus remarks, that the anatomy of the parts of fructification ſhows that all theſe varieties make but one ſpecies.

Native of Europe, Barbary and Siberia, on ſea coaſts, ſalt marſhes and æſtuaries, or the banks of great rivers expoſed to the tide; flowering through july and auguſt. At Sheerneſs and the Iſle of Dogs. Near Yarmouth. Shirley wych near Stafford. Between Stockton and Porterack, by the Tees, &c.

The Biſhop of Drontheim informs us that it is very greedily devoured by all ſorts of cattle. Mr. Curtis ſuggeſts, that ſwine being extremely fond of the roots of *Sc. paluſtris*, which the Swediſh peaſants collect and fodder them with in the winter, and the roots of this ſpecies being much larger, it would probably be preferable to that for this or ſimilar purpoſes.—Dr. Withering relates, that the roots, dried and ground to powder, have been uſed inſtead of flour in times of ſcarcity.

Monſ. Villars obſerves of the Scirpi in general, that being moſtly natives of bogs, marſhes and watery places, they have a tendency to raiſe and dry ſuch ſpots. The roots and baſe of the ſtems rot and become turf, and thus are uſeful for firing, and to fertilize grounds that we have exhauſted by a long courſe of culture.

54. Culm erect, with the angles acute. Leaves ſheathing, long, keeled, acute, ſtriated, quite entire; the lower ones ſhorter. Spikelets from three to ſix, blunt, pale, ſingle or two together from the top of the peduncles; which are three-ſided, pubeſcent, unequal, ſhort; the lower ones longer. Scales imbricate, ovate, concave, ſtriated, mucronate, membranaceous at the edge. Spikelets ſometimes ſeſſile.—On banks of lakes near La Calle in Barbary, flowering in ſummer [n].

55. Culm a fathom high, almoſt as thick as the human finger, erect, the ſides flat, very ſmooth, towards the root clothed with radicate lanceolate very ſmooth ſomewhat warted leaves. Spikelets ovate, ferruginous. Leaflets of the involucre rugged at the edge and one of them very long. It is very like *S. miliaceus*, but differs much in thickneſs and ſize.—Native of the Eaſt Indies [o].

56. Culm more than a foot high, even. Univerſal involucre many-leaved: leaves enſiform longer than the umbel. Partial involucres ſcarcely any except a very ſhort briſtle. Middle peduncles of the umbel very ſhort; all terminated by a little head, which is again proliferous. Heads roundiſh, compoſed of roundiſh ſpikelets in a ball.—Native of the Eaſt Indies [p].

Introduced in 1776, by Lady Ann Monſon: and flowering here in auguſt and ſeptember [q].

57. Culm ſolitary, erect, ſmooth. Leaves widiſh, rugged at the edge, thoſe next the root cloſely tufted; ſtem-leaves ſheathing, alternate; floral-leaves ſeſſile. Cyme many-flowered, ſuperdecompound, with three-ſided, rugged, alternate peduncles, and lanceolate membranaceous bractes. Spikes ſmall, ſolitary or heaped, ovate, duſky green. Glumes keeled, bluntiſh, undivided. Seeds ſurrounded by briſtles longer than the ſeed itſelf [r].

Native of Europe and Siberia in wet woods and ſhady places: as in Eſſex, Warwickſhire and Pembrokeſhire. Mr. Dale obſerved it by the river Blackwater, below Bocking. Mr. Newton, by the road to Kentiſh Town, a little beyond Pancras church [s]. Dr. Smith in Charlton wood. It has been ſeen formerly between Hampſtead and Highgate. Mr. Stone found it at Ditchingham, and Dr. Smith, in other parts of Norfolk [t]. Dr. Sibthorp, in Heythorp woods, Oxfordſhire. Ray, by the Thame ſide near Tamworth in Warwickſhire; in a brook near Haverford-weſt in Pembrokeſhire, and many other places [u]. Morton, between Kettering and Thorp-Malſor in Northamptonſhire. Deering, near Nottingham. Mr. Aikin, in a ditch near York. And Mr. Brown, a little eaſt of Breakinbridge over the South Eſk, on the ſouth ſide. It flowers in july [x].

58. Culm two feet high. Leaves ſheathing at the baſe. Corymb terminating, with the middle peduncles longer and proliferous. Between the pedicels a leafy briſtle. Spikelets ferruginous, compoſed of imbricate ſcales, of which the upper ones are longer and convolute into a ſubulate ſpike. There is a ſimple peduncled corymb from the axil of each ſtem-leaf.—Native of the Eaſt Indies [y].

According to Swartz, *Sc. corymboſus* of *Syſtema Vegetabilium*, is the ſame with his *Schoenus ſurinamenſis*.

59. Culms filiform, two inches high. Leaves filiform, channelled, commonly longer than the culm, rough-haired, ſheathed at the baſe. Umbels with ſimple and umbelled peduncles. Involucres filiform, rough-haired, compoſed of from five to eight leaves, three of which are longer than the umbel. Involucrets ſhort, capillary. Spikelets ſomewhat angular. Scales brown, keeled, acuminate with the points divaricating. Found abundantly in Ceylon by Koenig [z].

60. Leaves radical, ſetaceous, channelled, erect, ſhorter than the culm. Culms from a hand to a foot in height. Involucre terminating two-leaved: leaflets ſetaceous, one ſcarcely longer than the ſpikes, the other often ſix times as long and more upright. Spikes heaped: ſcales awl-ſhaped, ſtanding out, knotted at the baſe, much imbricated.—Native of the Eaſt Indies [a].

61. Native of the Eaſt Indies.

62. Leaves radical linear, even, ſhorter than the culm. Culm a foot high, with one angle obliterated, ſo that it is in a manner irregularly quadrangular. Panicle-like that of *Juncus bufonius*, but ſhorter. Univerſal involucre ſhorter than the panicle. Spikelets acutely three-cornered, few-flowered. Scales, eſpecially the three outer, acutely keeled, mucronate, between which a ſtamen or two, or a piſtil only, with a ſmall oblong germ, a ſimple ſtyle, and three long villoſe ſtigmas.—Native of China [b].

63. Height an inch or half an inch. Culm commonly reddiſh, naked or with a ſingle leaf at the baſe, the length of the ſcape. Head reddiſh. Involucre of two or three leaflets, the largeſt of which is twice or thrice the length of the head. Flowers one to four [c].

Leaves

Digitized by Google

Leaves keeled, even. Involucre of about five unequal leaflets, much longer than the head. Flowers in a close terminating head, simple or compound. Spikelets pale green, ovate, imbricate with acuminate loosish scales [d].

Native of Germany, France about Montpellier, Italy, Media, Morocco by the river Sebon. It is an annual, which is the case with very few of the species.

64. Culms a hand high, upright, loose. Stem-leaves four or five, alternate, grassy, wide, loose, sheathing, often the length of the culm. Peduncles axillary and terminating, shorter than the leaves, with from three to five sessile spikes at the end, divaricating into a head. Spikes ovate, imbricate, rough with thin-set hairs, blunt, mucronate with an awn shorter than the scales, erect, ciliate, distant. In place of an involucre, one or two small subulate leaflets under the head. Native of the East Indies. Annual [e].

65. Culms a foot high, strict, even. Leaves on the stem three, alternate, very remote, sheathing, grassy, somewhat keeled, even, acute, erect, several times shorter than the culm. Head compound, terminating, roundish, appearing to be simple but composed of several parcels of floscules heaped together. Scales terminated by a rough-haired slightly awned point. Involucre of the head three-leaved, unequal, scarcely longer than the head.—Native of the Cape of Good Hope [f].

66. Leaves radical, filiform, half-round on the outside, channelled on the inner side, length of the culm. Culms filiform, about a foot high. Head terminating, composed of numerous sessile equal spikes. Involucre setaceous, longer than the head, standing out laterally. Spikes ovate, imbricate in three rows, three-sided, brown with a pale edge, bluntish.—Native of the Cape of Good Hope and Guinea [g].

67, 68. Natives of the East Indies.

69. Culm lofty even striated. Head terminating, with the pedicels not conspicuous. Calyxes imbricate, acuminately squarrose or recurved. Universal involucre very long, three or four-leaved, reflexed, rugged at the edge [h].

S. cephalotes of Jacquin (hort. t. 97.) is quite a different plant from this of Linneus's [i].

S. junceus of Forster (prodr. n. 29.) a native of the Society Isles, seems, in Willdenow's opinion, to belong to the genus *Schoenus*.

S. capsularis of Loureiro, a native both of China and Cochinchina, is referred to the genus *Juncus*, by Willdenow. It has only three stamens, in which it agrees with this genus. (But as Willdenow remarks, some European species of *Juncus* have only three stamens.) It approaches in fructification to *Juncus*, in habit both to that and *Scirpus*, in calyx and corolla to neither. Loureiro chose to place it among the *Scirpi*, because there are many species of *Scirpus* in India, but few of *Juncus*.—The culm furnishes an excellent wick for candles and lamps. Juncus indicus porosus. *Clus. eur. post.* 64. seems to be this species [k].

SCIRPUS. See *Bobartia*, *Carex*, *Eriophorum*, *Juncus*, *Schoenus*, *Scleria*.

SCIURIS.

Lin. gen. Schreb. n. 53. Raputia. *Aubl. t.* 272. *Juss.* 421.

Class. 2. 1. Diandria Monogynia.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-toothed, short, acute.

COR. one-petalled, tubular, curved in, two-lipped. Upper lip trifid, with the middle segment a little longer: lower, a little shorter, bifid.

STAM. *Filaments* two, short, inserted into the upper lip, fenced by two scalelets at the base, antheriferous; three longer, inserted into the lower lip, hairy at the base, barren. *Anthers* oblong, bifid at the base.

PIST. *Germ* five-cornered, surrounded by a gland. *Style* length of the corolla, curved in. *Stigma* flattish, three-lobed.

PER. *Capsules* five, united, outwardly rounded, depressed, one-celled, two-valved, opening inwardly.

SEEDS solitary, oblong.

ESSENTIAL CHARACTER.

Cor. unequal, with the upper lip trifid, the lower bifid and shorter. *Stam.* five, but three barren. *Capsf.* five, united, one-celled, one-seeded.

SPECIES.

1. Sciuris aromatica.
Lin. spec. ed. Willd. 1. 153.
Raputia aromatica. *Aubl. guian.* 670. *t.* 272.

DESCRIPTION, *&c.*

This is a shrub, two feet in height, with opposite divaricating branches. Leaves opposite petioled ternate: leaflets oblong acuminate quite entire. Spikes axillary nodding [l].

The leaves have pellucid dots scattered over them. Each flower has a little bracte. It is allied to *Monniera* of Linneus, and *Galipæa* of Aublet [m].

Native of Guiana, in woods.

SCLAREA. See *Salvia*.

SCLERANTHUS. (*From* σκληρος *hard or juiceless, and* ανθος *a flower.*)

Lin. gen. n. 562. *Reich. n.* 611. *Schreb. n.* 767. & *p.* 831. *Gærtn. t.* 126. *Juss.* 314. Knawel. *Dill. gen.* 3.

Class. 10. 2. Decandria Digynia.

Nat. order of *Caryophyllei*. *Portulaceæ*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, tubular, half-five-cleft, acute, permanent, contracted at the neck.

COR. none.

STAM. *Filaments* ten, awl-shaped, erect, very small, placed on the calyx. *Anthers* roundish.

PIST. *Germ* roundish. *Styles* two, erect, capillary, length of the stamens. *Stigmas* simple.

PER. none.

SEED single, (or two) ovate, inclosed in the cartilaginous tube of the calyx.

ESSENTIAL CHARACTER.

Cal. one-leafed, inferior. *Cor.* none. *Seeds* two inclosed in the calyx.

Calyxes of the fruit fpreading very much and fpiny, ftem fubvilloſe.

DESCRIPTIONS, *&c.*

1. Root annual, fibrous, fmall but ſtriking deep, little or not at all branched. Stems very numerous, ſpreading in all directions, the outermoſt decumbent at the baſe only, not proſtrate their whole length, all round, a little downy, branched at top, leafy, pale ſometimes reddiſh. Leaves oppoſite, united at their baſe by a dilated membranous downy margin, linear, acute, ciliate at the bottom, of a graſſy green. Heads of flowers of the ſame colour, ſeſſile, terminating, leafy. Calyx with ten ribs, and cloven half way down into five ſharp ſpreading ſegments a little membranous at their edges. Stamens ſhorter than the calyx, ſometimes ten, but generally from five to eight, of which ſeveral are ſhort and imperfect. Germ ſuperior, ovate. Styles ſpreading. Stigmas downy. Seed incloſed in the permanent hardened calyx, often ſolitary, (as Dillenius, Haller, Leers, Adanſon and Gærtner remark) but there are certainly rudiments of two ſeeds, though one of them is commonly abortive [n]. Branches either oppoſite or alternate, always woolly. Leaves ſmooth above. Stamens ſix to nine, generally eight, two or three of them twice as long as the reſt and producing pollen, the others barren [o].

According to Leers the ſtamens are from five to ſeven; Gærtner ſays from five to ten. The latter deſcribes the pericarp as formed from the ripened calyx, coriaceous-ſuberous and almoſt nucamentaceous, involving the ſeed and not parting from it. Seed one, ovate-acuminate, ſmooth, pale ſtraw-colour: covering three-fold: the outmoſt from the calyx, hard, perforated at the top; the middle, membranaceous, looſe, bearing the ſtyle; the inmoſt like a cobweb. The middle integument might, with Linneus, be conſidered as a utricular capſule.

Native of Europe and Siberia.—Scarcely any plant is more common than this on a ſandy ſoil, eſpecially in fallow fields. It flowers about the middle of ſummer, and ſows its ſeeds very abundantly in autumn, which produce a crop of young plants that generally ſurvive the winter, or, if deſtroyed, are replaced by another crop ariſing from thoſe ſeeds that happen not to vegetate till ſpring [p].

The Swedes and Germans receive the vapour ariſing from a decoction of it into their mouths, to cure the tooth-ach [q].

2. Root perennial, as it is ſaid. It has the habit of the preceding, but the ſtems are perfectly proſtrate, and cloſe preſſed to the ground, downy in the upper part, much branched eſpecially towards their extremities. The colour of the whole herb is glaucous, and ſomewhat glittering with ſhining pellucid tubercles. Leaves ſometimes pubeſcent. Segments of the calyx with a wider membranous border than in S. annuus; their points much more obtuſe and curved inwards. The earlier flowers at the end of ſummer are of a very ſilvery appearance, and attract the eye at a diſtance. The ſtamens are ſeldom or ever all perfect. Calyx, in the flowering ſtate cloven rather more than half way down, but not ſo when the germ ſwells, externally pubeſcent. The whole plant when growing old becomes of a reddiſh brown [r].

Stems ſometimes, but not always woolly. Leaves ſea-green, fringed at the edge. Calyx not perfectly cloſed, but leſs open than in *S. annuus* [s].

Native of Europe and Siberia. In England at leaſt it is much more rare than the preceding, having hitherto been obſerved only in Norfolk and Suffolk; always on the drieſt barren ſandy heaths. Mr. Ray firſt found it at Elden in Suffolk, between Newmarket and Thetford. It has been ſince diſcovered about Bury by Sir Thomas Gery Cullum, Mr. Woodward, and Mr. Mathew; and near Snettiſham in Norfolk by Mr. Crowe. It flowers in november.

The Poliſh Cochineal (Coccus polonicus) is found upon the roots in the ſummer months: hence ſome authors have a variety of this ſpecies, under the name of Polygonum cocciferum [t].

3. Root annual. Stem branching and procumbent, a little villoſe and aſh-coloured, as are alſo the leaves. Flowers terminating, whitiſh, with a calyx ſlightly membranaceous. Anthers twice as large as in the firſt ſpecies [u].—Native of France and Italy.

Miller mentions the two firſt ſpecies, but gives neither character nor deſcription.

Lightfoot (app. 1134.) informs us, that the third ſpecies is ſaid to have been found at Broomholm near Langholm in Eſkdale, Scotland: but this report has not been confirmed.

SCLERIA. (*So named by Bergius; from* Σκληρος, *hard; on account of the hardneſs of the ſeed and whole plant.*)
Lin. gen. Schreb. n. 1403. *Berg act. holm.* 1765. *t.* 4. *Retz.* 4. 13. *Gærtn. t.* 2. *Swartz prodr.* 18.
Claſſ. 21. 3. Monoecia Triandria.
Nat. order of *Calamariæ*.

GENERIC CHARACTER.

Male flowers in the ſame ſpikelet or panicle mixed with the females.

* *Male ſpikelets* ſolitary, or androgynous.

CAL. *Glume* from two to ſix-valved, many-flowered: *valves* ovate, acute, keeled, concave, awnleſs, permanent.
COR. *Glumes* very many, oblong, awnleſs, longer and more ſlender than thoſe of the calyx, ſeparating the ſtamens.
STAM. *Filaments* ſolitary or three, within each corolline glume. *Anthers* linear.

* *Female ſpikelets* ſolitary, axillary, terminating, or inſerted between the male calycine glumes.

CAL. *Glume* two to four-valved, one-flowered: *valves* ovate, acute, awnleſs, keeled, concave, permanent.
COR. none.
PIST. *Germ* roundiſh, attenuated at the baſe. *Style* filiform, length of the glumes, undivided or trifid. *Stigmas* capillary, reflexed.
PER. none.
SEED. *Nut* ſubglobular or oblong, coloured, ſhining. *Nucleus* roundiſh, veined.

ESSENTIAL CHARACTER.

MALE. *Cal.* Glume from two to ſix-valved, many-flowered awnleſs.
Cor. Glumes awnleſs. *Filam.* one to three.
FEM. *Cal.* from two to ſix-valved, one-flowered, awnleſs. *Stigmas* one to three.
SEED. *Nut* ſubglobular, ſomewhat bony, coloured.

Culm three-ſided leafy erect even, leaves broad-lanceolate nerved, flowers panicled.

7. Scleria poæformis.
Retz. obſ. 4. 13.
Culm leafleſs, panicles contracted with flexuoſe branches, ſpikelets ſeſſile, female ſpikes axillary, males two-flowered.

8. Scleria tenuis.
Retz. obſ. 4. 13.
Culm leafy, leaves unarmed, panicle capillary, flowers ſeſſile, outer male, inner female.

9. Scleria lævis.
Retz. obſ. 4. 13.
Culm leafy, leaves unarmed, branches of the panicle divided involucred, male ſpikes ſeſſile and peduncled.

DESCRIPTIONS, *&c.*

1. Culm climbing very high, flaccid, ſubdivided, ſtriated, hiſpid with very minute briſtles, and the angles rugged with very ſhort recurved prickles. Leaves ſheathed, a foot long, linear, acute, ſtriated, keeled, ſmooth above with a longitudinal hiſpid line, hiſpid beneath, with the keel and edges prickly backwards. Sheaths ſtrict, ſhort, with a truncate hairy ligule. Panicles axillary, on compreſſed prickly peduncles from the ſheaths of the leaves; ovate with ſimple ſpreading ſubvilloſe branches. Floral leaflets briſtle-ſhaped, ſhort at the baſe of the branches and pedicels of the panicle. Pedicels alternate ſurrounded at the baſe by a little ſheath. Males mixed with the females. In the males, the calycine glume is ſix-valved, with the upper valves larger, all compreſſed at the top. Glumes of the corolla membranaceous, lanceolate. Filaments three or fewer, ſetaceous, length of the corolline glumes.—In the females, glumes from four to ſix-valved; the inner valves ſhorter. Germ oblong, bluntly three-cornered. Stigma ſimple, acute. Nut placed on the baſe of the permanent calyx, globular, brown and white variegated, with a tubercled whitiſh top[x].

According to Gærtner, the male ſpikelets are oblong, pyramidal, imbricate with ovate-acuminate ſcales; of which the lower are leſs and empty, the upper gradually longer having three ſtamens within each. The female ſpikelets are ſeſſile, imbricate with from four to ſix rigid ſmooth ſcales; of which the lower are leſs, and the two uppermoſt very large, ovate-acuminate, hemiſpherical-concave when ripe. Corolla at the bottom of the calyx three-petalled: petals rounded, concave, membranaceous, very thin white and ſmall. Nut coriaceous-cruſtaceous, globular depreſſed a little, produced below into an umbilical tubercle, ſmooth, ſhining, white or tinged with violet, one-celled, valveleſs. Seed or kernel one, of the ſame form with the nut, bay with branched veſſels.—Gærtner does not ſeem to have diſtinguiſhed this ſpecies from the *lithoſperma*.

Though Linneus placed it firſt in *Schoenus* and afterwards in *Carex*, he ſeems to have been well aware of its difference from both.

Sloane ſays it runs fifteen feet high among buſhes, ſupported by them; that there is a hollow between the angles of the culm, as in a ſword-blade; that the culm and leaves are of a very dark green; and that the ſeed which comes out between two black glumes, is roundiſh, large, whitiſh like that of Gromwell or pearl Barley.

Native of Jamaica, Surinam, and Africa.

2. Culm erect, ſcandent, without knots, ſmooth, with the angles even. Leaves lanceolate-linear, ſlightly keeled, widiſh, ſtriated, paler, ſmooth on both ſides. Sheaths long, cloſe, ſmooth; with a lanceolate blunt ligule. Panicles from the ſheaths of the upper leaves, elongated, contracted; with the branches ſimple, alternate, three-ſided, ſmooth. Flowers ſmaller on very ſhort pedicels. Glumes of the calyx and corolla in the males a little more ovate than in the preceding. Filaments three. In the females, glumes one-flowered; the inner ones larger. Nut placed on the calyx, globular, ſnow-white, black and tubercled at the top, girt at the baſe by a little ciliate membrane.—Native of Jamaica and Surinam[y].

Swartz ſuſpects it may poſſibly be the climbing Carex of Browne; the ſtalk of which he ſays is ſlender, and riſes to a conſiderable height, when ſupported by buſhes.

Native of the Eaſt Indies, Africa near the Cape of Good Hope, and the Iſle of Tanna in the Pacific Ocean. It approaches to the latifolia, but the culm is rugged, and the leaves are linear with the edges rugged.

4. This is a tufted graſs. Culm from one to two feet high, erect, looſe, ſharply three-ſided, ſmooth. Leaves linear, keeled, acute, alternate, ſeſſile not ſheathing, hiſpid at the edge, and (when examined with a magnifier) cartilaginous-ſerrate, ſmooth. Spikes terminating, ſimple; or peduncles from two to four, alternate, few-flowered; on which are floſcules from three to ſix, male and female mixed, ſeſſile, approximating with a capillary leaflet under them at the baſe. Under the valves are a few very ſmall ſcales. In the males, glume of the calyx four-valved: outer valves ſmaller, keeled, acute, often purpliſh at the tip, cloſed. Glumes of the corolla many interior, ſmall, linear, acute, imbricate, whitiſh. Filaments one between the valves, length of the glumes of the males, by the ſide of the corolline glumes. Germ roundiſh, whitiſh. Style filiform, length of the glumes, three-parted to the middle. Stigmas capillary, reflexed. Nut oſſified, oblong or roundiſh bluntly three-cornered, white, very hard, incloſing the ſeed. It approaches to *lithoſperma*, but the culm is ſimple and ſhort, and the flowers not panicled but in a ſort of ſpike.

Native of Jamaica and Hiſpaniola, in very dry rocky places.

5. This graſs is ſcarcely a foot high. Roots ſmall, filiform, black. Culm erect, three-ſided, ſtriated, looſe. Leaves ſlightly ſheathing at the baſe, diſtant, very narrow, ſlightly keeled, rough-haired. Spike terminating, compoſed of three or four cluſtered floſcules, which are ſeſſile, alternate, rough-haired. In the males, the glumes of the calyx are from two to four-valved, two-flowered, awnleſs: valves lanceolate, acute, ciliate at the edge with ferruginous hairs: one or two glumes, interior, more tender, ſmaller, corolline. Filaments ſolitary.—Females in the ſame bundle, ſolitary. Glume two-valved, one-flowered: valves broad-lanceolate, ciliate. Style bifid or trifid. Stigmas villoſe, reflexed. Nut oſſified, globular, ſhining, white. Very different from *filiformis* at firſt ſight.

Native of Jamaica.

[x] Swartz.

[y] Idem.

6. This

Digitized by Google

6. This graſs is a fathom in height. Culm undivided. Leaves from one to two feet in length, ſheathing at the baſe, often an inch wide, folding longitudinally, rigid. Sheaths acuminate in front. Panicles terminating, or from the axils of the upper leaves erect, ſtrict, ſomewhat branched; branchlets alternate, with male and female flowers ſcattered, diſtinct, ſubſeſſile or pedicelled, having a ſmall leaf always under the floſcules. Males terminating: glume of the calyx three or four-valved, two or three-flowered: valves ovate, acute, keeled, permanent, ſmooth. Inner corolline glumes ſmaller, narrower. Filaments three, very minute.—Females more numerous, below the others. Glume four-valved, one-flowered: the two outer valves lanceolate, the two inner broad-ovate, acuminate, permanent. Germ roundiſh. Style trifid at the top and permanent. Stigmas reflexed, villoſe, whitiſh. Seed globular, ſomewhat bony, marked with a whitiſh point ſtanding out.

Native of Jamaica, eſpecially in the weſtern parts, in dry mountain woods [z].

7. Culm three-cornered, with flat ſides. Common peduncle of the panicle multangular; the others triangular. Male ſpikelets cylindrical, alternate. Under each branch of the panicle a capillary leaflet. It has almoſt the appearance of a Poa.

Native probably of the Eaſt Indies, ſince it was ſent by Koenig.

8. This has the appearance of a ſlender ruſh. Leaves filiform. Panicle ſmall, little divided. All the flowers, except thoſe which are at the end of the branches, ſeſſile within the common ſcales, one male exterior and one female interior.—Koenig communicated it from Ceylon.

9. This has many things in common with *S. mitis* of Bergius. Male ſpikelets ſeſſile and peduncled; all the females ſeſſile. Under each branchlet of the panicle a leaflet or filiform involucre. Leaves and culm narrower.

Native of the Eaſt Indies [a].

SCLEROCARPUS. (*From* σκληρος *hard, and* καρπος, *fruit.*)

Lin. gen. Schreb. n. 1327. *Jacqu. fil. act. helv.* 9. 34. *t.* 2. *Gærtn.* 2. 428. *Juſſ.* 186.

Claſſ. 19. 3. Syngeneſia Polygamia Fruſtranea.

Nat. order of *Diſcoideæ. Corymbiferæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Common* of ſix leaflets, of which three are exterior, three interior, alternately: *exterior* biggiſh, of the ſame ſtructure and appearance with the leaves, ſpreading; two large, the third leſs: *interior* linear, channelled, acute, erect with a ſpreading tip, length of the floſcules.

COR. *Compound*, radiate: *Corollets* hermaphrodite ten in the diſk: *Female* three in the ray, each within one of the interior calycine leaflets.

Proper of the Hermaphrodites tubular, five-cleft:—of the Female ligulate, roundiſh.

STAM. in the Hermaphrodites *Filaments* five capillary. *Anthers* five, ſmall, united, each awned at the tip.

PIST. in the Hermaphrodites: *Germ* oblong, compreſſed, outwardly gibbous. *Style* filiform, length of the corollet. *Stigma* deeply bifid, revolute. In the Females, *Germ* ſlender. *Style* none. *Stigma* none.

PER. none, except the chaffs involving the ſeeds.

SEEDS in the Hermaphrodites ſolitary, oblong, compreſſed, with the outer margin gibbous, the inner ſtraight. *Pappus* none. The Females have no ſeed.

REC. convex, ſmall. *Chaffs* of the hermaphrodites cartilaginous, compreſſed, gibbous at the back, ſtriated and tubercled, opening at the inner ſtraight ſide, the margins converging inwards flat and even, the apex terminated by a ſhort almoſt upright neck: mouth oblique, acuminate outwards; each incloſing a ſingle ſeed. Chaffs of the Females ſtraightiſh, cylindrical, ſlender, ſhorter.

ESSENTIAL CHARACTER.

Cal. ſix-leaved, three exterior larger, like the leaves, three interior ſmaller, like ſcales, alternate. *Pappus* none. *Recept.* chaffy.

SPECIES.

1. Sclerocarpus africanus.

Jacqu. nov. act. helv. 1. 34. *t.* 2. *icon. rar. Lin. ſyſt.* 783. *Gærtn. fruct.* 2. 428.

DESCRIPTION, *&c.*

1. Herbaceous but ſomewhat woody, with alternate three-nerved leaves, and terminating ſolitary flowers. Florets in the diſk about eight fertile; in the ray from one to four, neuter. Chaffs permanent, hardening, acuminate. Seeds ovate, ſubcompreſſed, (or dimidiate obovate) remarkably narrowed downwards, black and ſhining, each wrapped up in the chaff [b].—Native of the Cape of Good Hope.

Claſſ. 12. 1. Icoſandria Monogynia.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, three or four-parted, permanent: *ſegments* ovate, obtuſe, concave, ſpreading.

COR. *Petals* three or four, oblong, ſubcoriaceous, obtuſe, ſpreading, permanent, twice the length of the corolla.

STAM. *Filaments* numerous, filiform, flattiſh below, villoſe at the baſe, ſpreading, permanent, length of the corolla, inſerted into the calyx. *Anthers* linear.

PIST. *Germ* roundiſh, ſuperior. *Style* cylindrical, ſtraight, longer than the ſtamens. *Stigma* thickened, three-lobed, impreſſed above with three little pits.

PER. *Berry* roundiſh, crowned with the permanent ſtyle, one-celled.

SEEDS ſix, rounded-four-ſided, arilled. *Arils* membranaceous, thin, pulpy, angular, two faſtened to three ribs, glued to the inner wall of the berry.

OBS. *The ribs eaſily ſeparate from the berry, and are reſolved into ſix unequal threads, from the apex of which the arils hang down.*

ESSENTIAL CHARACTER.

Cal. inferior, three or four-parted. *Cor.* three or four-petalled. *Berry* crowned with the ſtyle, one-celled, ſix-ſeeded. *Seeds* arilled.

SPECIES.

1. Scolopia puſilla.

Lin. ſpec. ed. Willd. 2. 981.

Limonia puſilla. *Gærtn. fruct.* 1. 279.

Malus limonia lentiſci folio zeylanica, fructu minimo uvariæ magnitudine. *Pluk. alm.* 239.

DESCRIPTION, *&c.*

Berry elliptic-ſphæroidal, crowned with a ſhort ſtyle, fleſhy-coriaceous, divided within into three incomplete cells by three prominencies. Pulp ſeparated every way from the cells by a very thin membrane, and formed into three ſoft oblong bags, in which the ſeeds are lodged. There are generally two ſeeds in each bag, ſeldom three, placed on each other, obliquely and irregularly truncate at the point of contact, in other parts ſubovate, convex on one ſide, angular on the other, black and ſomewhat ſhining.

Native of Ceylon, where it is called *Khatu-Kurundu*, or thorny Cinnamon; whence we may conjecture that it reſembles the Cinnamon in leaves and outward appearance, but differs from it in having thorns [c].

SCOLOSANTHUS. (*From* σκωλος *a thorn, and* ανθος *a flower.*)

Vahl ecl. 1. 11. *t.* 10.

Claſſ. 4. 1. Tetrandria Monogynia.

Nat. order of *Luridæ. Rubiaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, ſuperior, ſmall, four-cleft: *ſegments* linear-lanceolate, four times ſhorter than the corolla, acute, ſpreading.

COR. one-petalled with claws, tubular, before it opens exactly four-cornered, the angles acute, a little curved in, gradually widening upwards; when opened bluntly four-

four-cornered. *Border* four-cleft: *ſegments* ovate, acute, revolute.

STAM. *Filaments* four, erect, ſcarcely placed at the bottom of the corolla, cohering a little at the baſe in a four-cornered ſmooth tube, a little hairy below. *Anthers* linear, erect, the length of the tube.

PIST. *Germ* inferior, ſmall. *Style* capillary, a little longer than the corolla. *Stigmas* two, ſmall, obtuſe, a little thicker than the ſtyle.

PER. *Drupe* ſubglobular, ſize of black pepper, ſmooth, ſucculent, mucronate with the permanent calycine ſegments.

SEED one, in an oblong, ſomewhat ſtony, one-celled ſhell.

ESSENTIAL CHARACTER.

Cal. four-cleft. *Cor.* tubular with a revolute border. *Drupe* one-ſeeded.

SPECIES.

1. Scolopanthus verſicolor.
Lin. ſpec. ed. Willd. 1. 607. *Vahl ecl.* 1. 11.
Cateſbæa parviflora. *Lamarck encycl. & meth. bot.* 1. 67.

DESCRIPTION, &c.

This is a ſmall ſhrub, approaching in habit to *Juſticia ſpinoſa*. Branches round, alternately compreſſed at top, remote, commonly oppoſite, rarely alternate, ſometimes bifid, the thickneſs of a packthread, green with a tinge of aſh-colour, appearing pubeſcent when examined by a magnifier, jointed, the internodes about half an inch in length; the joints ſurrounded by a ſort of ring formed by the ſhort evaneſcent membrane of the ſtipules. Leaves ſubſeſſile, oppoſite, from two to five on each ſide, more ſeldom ſolitary, ſcarcely half an inch long; others a little ſmaller, obovate, quite entire, ſubcoriaceous, veinleſs, nerveleſs, ſhining. Spines commonly in pairs, from each alternate axil, connate at the baſe, divaricating, for the moſt part a little longer than the leaf, rigid, purpliſh, often floriferous at one of the tips. They are the younger ſpines that commonly bear the flowers, and they keep growing on after the flowers are fallen. Flowers on very ſhort peduncles: thoſe from the apex of a ſpine ſolitary, a little ſmaller, moſtly drooping, purple, abortive: others axillary, ſolitary or more rarely two or four together, erect, ſaffron-coloured, fertile. Fruit ſnow-white. Diſcovered in the iſland of Santa Cruz by Ryan [d].

SCOLYMOCEPHALA, SCOLYMOCEPHALUM. See *Protea*.]

SCOLYMUS (*of Pliny*, Σκολυμος *of Dioſcorides, and Heſiod. Theophraſtus has* σκολυμωδες φυλλον.)
Lin. gen. n. 922. *Reich. n.* 1001. *Schreb. n.* 1252. *Tournef. t.* 273. *Vaill. act. gall.* 1721. 41, 42. *Juſſ.* 171. *Gærtn. t.* 157. *Desfont. t.* 218.
Claſſ. 19. 1. Syngeneſia Polygamia Æqualis.
Nat. order of *Compoſitæ Semifloſculoſæ. Cichoraceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Common* imbricate, ovate: *ſcales* numerous, lanceolate, ſpiny, looſe.

COR. *Compound* imbricate, uniform: *corollets* hermaphrodite, numerous, equal.
Proper one-petalled, ligulate, linear, truncate, very finely five-toothed.

STAM. *Filaments* five, capillary, very ſhort. *Anther* cylindrical, tubular.

PIST. *Germ* oblong. *Style* filiform, longer than the ſtamens. *Stigmas* two, reflexed.

PER. none. *Calyx* unchanged.

SEEDS ſolitary, ſomewhat oblong, triangular, acuminate at the baſe. *Pappus* none.

REC. chaffy, convex: *chaffs* roundiſh, flat, three-toothed at the tip, longer than the ſeeds and ſeparating them.

ESSENTIAL CHARACTER.

Cal. imbricate, ſpiny. *Pappus* none. *Recept.* chaffy.

Flowers ſolitary, the upper ones approximating, involucres coriaceous nerved lanceolate acute.]

DESCRIPTIONS, &c.

1. This is an annual plant, which riſes with a branching ſtalk four or five feet high, having leafy wings running along the ſides from joint to joint, ſcalloped and indented; the borders of theſe are thinner than the other parts, and are armed all the way with very ſharp ſpines; at each joint are ſtiff leaves, which are jagged and armed with ſtrong ſpines; they are pale green and ſeſſile. The flowers are produced at the top of the ſtalks incloſed in leafy involucres, longer than the flowers, and armed with very ſtrong ſpines: within theſe the calyxes are armed with ſhort ſpines. The flowers are compoſed of many golden florets.

[It is an annual herb, with a ſlender root. Stem more branched below. Leaves ſmooth, ſhining, with a cartilaginous border, decurrent almoſt to the baſe of the ſtem. Flowers ſolitary from the divarications. Corolla ſmaller with brown anthers [e].

According to Gærtner, the flowers of this are larger and moſtly ſolitary, and the leaves are thickened at the edge. But theſe marks are by no means certain or conſtant, the true ſpecific difference therefore ought to be taken from the chaffs of the receptacle not involving the ſeeds. Hence he has named it *gymnoſpermos*.

Root fuſiform, often branched. Stems ſubvilloſe, with the wings unequally toothed and ſpiny. Branches numerous, ſpreading. Stem-leaves rigid, ſpiny, variegated with white ſpots, ſinuate-lobed, with cartilaginous edges, unequally toothed, the teeth ſpiny. Flowers ſolitary or aggregate on a common peduncle along the branches and from the point of diviſion. Bractes four or five, coriaceous, pectinate, cartilaginous at the edge, longer than the corolla: teeth long, almoſt equal, awl-ſhaped, ending in a prickle. Corollets linear, toothed at the end, yellow. Anthers brown. Seeds even, convex on one ſide, neſtling in the chaffs of the receptacle (which is contrary to Gærtner's opinion.) Receptacle conical. Chaffs ſhort, blunt. It differs from the others in having an annual root, the upper leaves cartilaginous at the edge, the bractes pectinate, the flowers ſmaller, the anthers brown, and

[e] Linn. ſyſt.

the

Digitized by Google

the ſeeds being deſtitute of a pappus or down. There is a great confuſion of ſynonyms in Gærtner[f].

Native of the South of Europe, and of Barbary.—This, ſays Johnſon, (in Ger. emac.) I ſaw this year (1633,) growing in the garden of Mr. John Tradeſcant, ſenior, at South Lambeth.]

2. Root perennial (biennial,) from which ſpring up many thick ſtalks, that riſe about three feet high, branching out on the ſides the whole length, and having ſtiff jagged leaves, the borders of which are thicker than the other part, and armed with ſpines as in the preceding: the ſtalks alſo have leafy borders as the other, ſtrongly armed with ſpines. The flowers are produced at the top of the ſtalks, and are ſhaped like thoſe of the former ſort. They ſit cloſe, and are ſo cloſely guarded by long leaves armed with ſtrong ſpines, that it is very troubleſome to reach the flower.

[This flowers the ſecond year, and has a fuſiform root. Stem leſs branched below. Leaves ſomewhat rugged, aſh-coloured, not cartilaginous at the edge, decurrent, but ending before the next leaf. Flowers commonly four, heaped or aggregate. Corolla double the ſize of the other with anthers of the ſame colour[g].

According to Gærtner, the calyx when mature is ſmaller than that of the preceding, and fenced with narrower leaves: the receptacle very convex and almoſt globular: the chaffs membranaceous, obovate, folded together by the edges bending inwards, and thus almoſt concealing each ſeed as in a ſheath, (whence he improperly names this ſpecies *angioſpermos*.) Seeds obovate, remarkably acuminate downwards, a little convex on one ſide and marked with a double longitudinal line, on the other flattiſh with a ſingle line along the middle. Integument ſingle, membranaceous, ſnow-white but not ſhining. The preceding, beſides this membranaceous coat, has an exterior one, that is coriaceous, thickiſh and hard. In that alſo the receptacle is almoſt flat; the chaffs oblong, keeled, ciliate, narrower than the ſeeds, which are naked, ovate, ſmooth, ſhining, pale ſtraw-coloured or ruſeſcent.

Allioni aſcribes a pappus, of two or three awns readily falling off, to this ſpecies, which Gærtner has never ſeen in cultivated plants. He adds that Ehrhart affirms of the ſeed of Scolymus that it is two-awned, but he does not mention the ſpecies.

Deſfontaines deſcribes the root as fuſiform, often branched; the branches of the ſtem ſpreading, villoſe, winged; the wings ſpiny, unequally toothed, the teeth ending in a prickle; the flowers ſeſſile, ſolitary or aggregate; the bractes (involucre) torn, rigid, lanceolate, leafy, channelled, a little longer than the flower, unequally tooth-ſpiny at the edge, acute; ſcales of the calyx linear-lanceolate, often ending in a prickle; corollets yellow, linear, attenuated upwards, toothed at the end; anthers yellow; ſeeds even, obovate, convex on one ſide, neſtling in the chaffs of the receptacle, having two or three deciduous awns; receptacle hemiſpherical, with ſhort blunt chaffs. It differs from the next ſpecies, to which it is allied in having a branched, loftier ſtem, the leaves ſemidecurrent, the bractes leafy, the flowers numerous ſometimes aggregate, and the corollas ſmaller by half.

Deſfontaines conſiders it as biennial. Miller ſays it will continue ſeveral years.

Villars is diſpoſed to make one ſpecies of theſe. The firſt, he ſays, is annual; the leaves ſmooth, ſpotted with white like our Lady's Thiſtle, and a cartilaginous border; the ſtems are more branched, leſs ſtraight, as are alſo the roots, and the flowers are at the ends of the branches, commonly by threes, and ſomewhat ſmaller.

The ſecond has the leaves more cut, not ſo thick, larger, and a little pubeſcent; the ſtem ſtraight, commonly ſimple, with axillary flowers having the calyx a little villoſe; the root is perennial, ſimple and fuſiform; ſoft and ſweet like Scorzonera, and as good to eat as that.]

Mr. Miller ſays, that the leaves, ſtalks and root abound with a milky juice; that the people of Salamanca eat it in the ſame manner as Chardon, and that the Spaniards ſophiſticate their Saffron with the flowers.

[Native of the South of Europe, and of Barbary. Cultivated in the botanic garden at Oxford, in 1658. It flowers from july to ſeptember. The preceding in july and auguſt[h].

3. Root perennial, fuſiform, white, the thickneſs of a finger. The whole plant milky. Stem ſimple or very ſparingly branched, erect, villoſe, winged: wings unequally tooth-ſinuate: teeth ſpiny at the end. Leaves alternate, rigid, decurrent, long, variegated with white veins, ſinuate-lobed; lobes ovate and lanceolate, acute, unequally toothed; teeth ending in a prickle. Flowers axillary, ſolitary, ſeſſile, three four or five from the top of the ſtem; the lower for the moſt part more remote. Bractes (involucre) three, involving the calyx, (in the terminating flower ſix,) thick, coriaceous, lanceolate, channelled, acute, painted longitudinally with white and green nerves; toothed at the edge with rigid, uniform, remote, horizontal teeth, ſpiny at the end. Scales of the calyx linear-lanceolate, ſmooth, frequently terminated by a ſpinule, membranaceous at the edge; the outer ſcales ſhorter, blunt; the inner acute. Corollets yellow, lanceolate, narrower at top, toothletted at the end. Anthers yellow. Seeds even, ſmooth, obovate, convex on one ſide, neſtling in the chaffs of the receptacle. Pappus has two or three deciduous brittle awns. Receptacle hemiſpherical, chaffy: the chaffs compreſſed and obtuſe.—This is a very beautiful ſpecies, flowering early in ſpring, and now cultivated in the European gardens.

Native of Egypt, and very common in the fallows of Barbary. The Arabs eat the ſtalks both raw and boiled[i].]

PROPAGATION AND CULTURE.

Sow the ſeeds in march or april, on a bed of freſh undunged earth, in an open ſituation; when the plants come up keep them clear from weeds, and thin them ſo as to leave them about two feet aſunder. As they ſend forth tap-roots, they do not bear tranſplanting well. If the ſeaſon ſhould prove warm and dry, they will perfect their ſeeds in autumn; but in wet ſeaſons they rarely perfect their ſeeds in England. In that caſe freſh ſeeds muſt be procured from abroad; or the ſecond and third may be increaſed by offſets.

Leaves lanceolate alternate quite entire, corymb ſuperdecompound trichotomous.]

DESCRIPTIONS, *&c.*

1. Root annual. Stalk hexangular, riſing near two feet high, and ſending out many branches, which have three leaves placed round at each joint; theſe are about an inch long, and a quarter of an inch broad, ſerrate, and of a deep-green colour: the flowers come out from the ſide of the ſtalks at each joint on peduncles: they are ſmall, white, and their petals have bearded threads on their edges.

[It is upright, and attains the height of three feet. Leaves oblong, acute, attenuated into the petiole. Peduncles one-flowered, axillary. The ſegments of the corolla have many hairs at the baſe equalling the ſtamens [k].

The branches, as well as the leaves, are in threes; the leaves ſeſſile and ſmooth [l].

Capſule ſmall, ſpherical, with a groove on each ſide, thin, two-celled and two-valved. (Loureiro ſays it is ovate and four-valved.) Partition membranaceous, very thin, diaphanous, parallel to the valves and faſtened to their future. Receptacle orbicular, depreſſed a little, ſpongy, faſtened along the partition on each ſide. Seeds numerous, ſmall, ovate-globular, obſcurely angular, having very minute holes in rows, ſomewhat of a ruſt colour [m].

Native of Jamaica and all the Caribbee iſlands and the neighbouring continent; alſo in Cochinchina.—The French call it *Balai doux* or Sweet Beeſom; the Spaniards *Eſcobilla menuda* or Little Beeſom. An infuſion of it is uſed by both in diſorders of the breaſt [n]. According to Browne, it may deſervedly be conſidered as an excellent vulnerary.

It was cultivated in 1730 by Mr. Miller; and flowers from june to ſeptember [o].

β. Piſo's plant, in his herbarium, was ſubvilloſe [p].

2. This plant is ſcarcely half a foot high, with nearly the ſame habit as the preceding; but with the ſtems dichotomous, procumbent at bottom and then upright. Leaves awl-ſhaped, acuminate, ſmall, ſtiffiſh, in fours with the two interior oppoſite ones a little ſhorter. Flowers white, ſeſſile, ſmall, in the forkings of the branchlets, and in ſome of the axils. The tube of the corolla is fringed at top, but there are no hairs at the baſe of the ſegments. In other reſpects it agrees with the preceding.

Native of Carthagena in New Spain, on the ſandy coaſt about Boca Chica [q].

3. This is a tree, having the habit of the Olive or of Phillyrea. The inflorescence is very large and extremely compounded. The flowers are ſmall.

Native of the Cape of Good Hope, where it was found by Thunberg [r].]

PROPAGATION AND CULTURE.

1. Sow the ſeeds upon a hot-bed in the ſpring; and when the plants are fit to remove, plant them upon a freſh hot-bed, ſhading and watering them, until they have taken new root; after which admit air to them daily according to the warmth of the ſeaſon, and refreſh them frequently with water. In june they may be taken up with balls of earth to their roots, and planted into open borders, where they will flower, perfect their ſeeds in the autumn, and ſoon after periſh.

2. Scopolia inermis.
Willd. ſpec. 1. 1116.
Toddalia. *Lamarck encycl. t.* 139. *f.* 2.
Stem unarmed, leaflets obovate obtuſe.

OBSERVATIONS.

This plant has already appeared twice in our Dictionary; firſt as the *Paullinia aſiatica* of Linneus; ſecondly as the *Cranzia* of Schreber; and here thirdly as the *Scopolia* of Smith.—The *Scopolia* of the younger Linneus's Supplement, is referred by Dr. Smith to the genus *Daphne*. The *Scopolia* of Jacquin is conſidered by the elder Linneus as a ſpecies of *Hyoſcyamus*. And the *Scopolia* of Forſter, has obtained another name of *Griſelinia lucida* from the author himſelf. That ſo eminent, though unfortunate a naturaliſt, ſhould not want a name, Dr. Smith has conſecrated this plant to his memory, with an elegant and handſome teſtimonial to Scopoli's great merits.—Juſſieu's and Lamarck's name *Toddalia*, from the Indian *Kakatoddali*, is barbarous. And another plant has received the name of *Cranzia*, from Swartz, in his Prodromus [s].

Willdenow remarks, that the leaves are ternate; the panicles racemed and axillary. For the reſt ſee *Cranzia* and *Paullinia aſiatica*.

2. This has the habit of the preceding, and alſo ternate leaves, but yet it is ſufficiently diſtinct by the ſtem being unarmed, the leaflets obovate, obtuſe, and the flowers in terminating corymbs. Suppoſed to be a native of the Iſle of Bourbon [t].

   Peduncles moſtly four-flowered, legumes with acute ſpines in cluſters outwardly.

DESCRIPTIONS, *&c.*

1. Stalks herbaceous, trailing, above a foot long, lying on the ground, and having at each joint a ſpatulate leaf on a long foot-ſtalk. Peduncles axillary, ſuſtaining at the top one yellow flower, which is ſucceeded, by a thick twiſted pod, the ſize and appearance of a large green caterpillar.

[Stem half a foot high. Leaves lanceolate, decurrent into the petiole, having flaccid villoſe hairs ſcattered over them above, acuminate, quite entire. Bractes in pairs, erect, narrow, attenuated, longer than the banner of the corolla. Peduncles near two inches in length, ſhorter than the leaf. Banner ſtriated with eight reddiſh lines at the baſe. Wings placed at the apex of the keel. Filaments widening at the top. Stigma ovate. Legume marked with ten raiſed warted ſtreaks [a].

Legume round, thick, rolled into a cloſe ſpiral, ſwelling a little where the ſeeds are; covered all over on the outſide with headed ſcalelets in longitudinal rows; divided within into ſix or nine cells, valveleſs and not ſeparating at the joints. Seeds ovate-globular, ſmooth, ſtraw-coloured or rufeſcent, faſtened to the outer ſide of the cells. Navel in the middle of the back [b].

Native of the South of Europe. Cultivated in 1621, by Mr. John Goodyer [c].]

2. This has ſtronger ſtalks than the firſt; the leaves are much broader; the peduncles ſupport two ſmaller flowers; the pods are ſlender, longer and more twiſted, and are armed with blunt ſpines on their outſide.

[Scopoli remarks, that it has the appearance, duration, ſtature, &c. of the preceding; differing only in having the peduncles two-flowered, longer than the leaf; and the pod rough with angular ciliate lines.

Native of the South of Europe.

It was cultivated here in 1640, as appears from Parkinſon [a].]

3. This has ſlenderer ſtalks than either of the former; the leaves ſtand upon ſhorter footſtalks, but are ſhaped like thoſe of the firſt ſort; the peduncles are ſlender, and frequently ſupport three flowers; the pods are ſlender, not ſo much twiſted as the former, and armed on their outſide with ſharp diſtinct ſpines.

[The pods are channelled more viſibly than thoſe of the preceding; and the briſtles are diſtinct and ſtiffer [b].——According to Gærtner, the legume is roundiſh, ſlender, rolled into a looſe waved ſpiral, jointed, grooved, four of the dorſal grooves ſpiny, the others, as alſo the ventral ones unarmed. Joints ſeven to ten, curved, valveleſs, not ſeparating. Seeds roundiſh, curved a little, ferruginous.

Native of the South of Europe, and Barbary about Algiers. Cultivated by Gerarde, in 1596 [b].

4. Stems ſtriated, ſubvilloſe, procumbent. Leaves wide-lanceolate, quite entire, petioled, ſubvilloſe, acute. Stipules narrow-lanceolate, acute. Peduncles axillary, naked, ſtriated, twice or thrice the length of the leaf. Flowers ſmall, in fours, terminating. Calyx half-five-cleft, with awl-ſhaped ſegments. Corolla yellow. Keel acute. Legume twiſted, echinate with numerous little briſtles [c].]

The ſtalks and leaves of this are very like thoſe of the firſt, but the peduncles are longer, and each has three or four ſmall yellow flowers at the top: the pods are very ſlender, greatly contorted, and armed with ſhort ſpines in cluſters on their outſide.

[Native of the South of Europe, and Barbary about Algiers.

Linneus ſays there is no doubt but that all theſe are originally derived from one ſpecies; that ſoil and ſituation are not adequate to their generation, for then, on changing theſe again, they would return to their former ſameneſs. What mixture then, he aſks, can have produced theſe conſtant plants? Whoever would either unite or diſtinguiſh them, might have arguments on his ſide.

Desfontaines has another ſpecies, which he names *Scorpiurus purpurea*. It is allied to the firſt ſpecies, and has one flower on a long peduncle, as that has: but the ſtems and leaves are hirſute: the corolla purple: the legume grooved and very ſhortly muricate, not ſcaly, as in *S. vermiculata*.

Native of Algiers.]

Mr. Miller has alſo another ſpecies with pinnate leaves, which he therefore names *Sc. pinnata*.—It has very ſhort ſtalks: the leaves have four or five pairs of ſmall leaflets, terminated by an odd one: the flowers are ſmall, as are alſo the pods, which are leſs twiſted than in the others.

[Gærtner remarks, that in this whole family or natural order, the embryo is not long and round, or ſhaped like the ſhaft of a column, (teres) except in *Hippocrepis* and this genus.]

PROPAGATION AND CULTURE.

Theſe plants are preſerved in ſeveral curious gardens, for their oddneſs more than for any great beauty: they are all of them annual plants, which are propagated by ſowing their ſeeds upon a bed of light freſh earth; and when the plants are come up they ſhould be thinned, ſo as to leave them about ten inches or a foot aſunder; becauſe their branches trail upon the ground; and if they have not room, they are apt to overbear each other, and thereby are very often rotted, eſpecially in moiſt ſeaſons. The weeds ſhould alſo be diligently cleared from them, otherwiſe they will grow over and deſtroy them. In june theſe plants will produce ſmall, yellow flowers, which are ſucceeded by

Digitized by Google

pods ſo much like caterpillars, that a perſon at a ſmall diſtance would imagine they were real caterpillars feeding on the plants; and it is for this oddneſs of their pods, that theſe plants are chiefly preſerved.

Theſe plants ſeldom thrive well if they are tranſplanted; therefore the beſt method is, to put in three or four good ſeeds in each place where you would have the plants remain; which may be in the middle of large borders in the pleaſure-garden, where, being intermixed with other plants, they will afford a pleaſing variety. When their pods are ripe, they ſhould be gathered and preſerved in a dry place till the following ſpring, in order to be ſown.

The firſt ſort is the beſt worth cultivating, the pods being large and more viſible than the others, and more in form of a caterpillar.

Leaves pinnatifid half-embracing, panicle diffuſed terminating.

DESCRIPTIONS, *&c.*

1. Stem ſtraight, ſimple, tomentoſe. Leaves alternate, ſcarcely half-embracing, ſharpiſh. Branches floriferous, axillary, ſolitary, one or two-flowered, ſcarcely longer than the leaf. One or two lanceolate bractes. Native of the Levant [d].]

2. This is ſhorter than *hiſpanica*; the leaves are broader; the ſtalk is almoſt naked, and has one yellow flower at the top.

[Root thick, ſtriking deep, having a thick tuft of briſtles at the top. Leaves ſmooth, firm, reſembling thoſe of Plantain or garden Tulip. Stem ſimple, ſix inches high, having two or three leaves. Scales of the calyx membranous at the edge, pointed, ſmooth and lanceolate at the end.

Others deſcribe the ſtem as a foot or eighteen inches in height. The root-leaves are many and form a tuft; they are four inches long, and three quarters of an inch wide. The pappus is ſeſſile [e].

Native of Europe.

3. Native of Auſtria.]

4. Root carrot-ſhaped, about the thickneſs of a finger, and covered with a dark-brown ſkin; it is white within, and has a milky juice. Lower leaves nine or ten inches long, and an inch and half broad in the middle, ending with a long acute point. Stalk three feet high, ſmooth, branching at top, and having on it a few narrow embracing leaves. Flowers bright yellow.

[Leaves ſcarcely wider than a finger, appearing to be very finely ſerrate, when examined by a magnifier [f].

Its branched ſtem, ſays Villars, and waved embracing leaves, diſtinguiſh this from the firſt ſpecies.

Sc. latifolia altera. *Bauh. pin.* 275. appears to be different from this. The leaves do not embrace the ſtalk, but are attenuated at their baſe; they are entire, not toothed, and more of an aſh-colour than in the Garden Viper's-graſs. Ammann ſeems to have it in his *Stirpes ruthenicæ, p.* 151. *n.* 213. Matthiolus has figured it under the name of *Sc. boemica*, and Camerarius (epit. 314.) under that of *Sc. hiſpanica*. Caſpar Bauhin, in his edition of Matthiolus, has repeated it; as has alſo Cluſius, *hiſt.* 138 [g]. Miller made a diſtinct ſpecies of it in the 7th edition of his Dictionary.

Native of Spain, the South of France, Italy, Carniola, Siberia, and the Levant.—Cultivated by Gerarde, in 1596 [h].

5. Root perennial, the thickneſs of the thumb, briſtly at the top with the dry fragments of the leaves of the former year. Stem herbaceous, erect, half a foot high, quite ſimple except that it has often a branch or two at the baſe almoſt as high as the ſtem, round, mealy-tomentoſe at top and bottom, leafed below. Leaves ſeſſile, linear-enſiform, often three inches long, obſcurely nerved, mealy-tomentoſe on both ſides, keeled, the loweſt narrowing to both ends, the upper ones widening at the baſe. Flower terminating, ſolitary, the ſame ſize as in *Sc. humilis*. The peduncle is ſcarcely thickened under the flower. Calyx only half the length of the ray: outer leaflets ovate, acuminate; inner ovate-lanceolate, all membranaceous at the edge. Corolla pale red. Anthers brown, with a ſaffron-coloured pollen. Stigmas ferruginous.—Common in parched ground in the kingdom of Tunis [i].]

6. Stalks ſlender, about two feet high, branching towards the top, and ſuſtaining pale-yellow flowers, ſmaller than in *hiſpanica* and *humilis*.

[Root perennial, brown on the outſide. Stem round, ſtriated, erect, the whole always leafy, ſometimes quite ſimple and one-flowered, ſometimes having a branch or two, ſlightly woolly in the lower part eſpecially at the axils of the leaves, otherwiſe ſmooth. Leaves ſcattered alternately, ſmooth, quite entire, acute, under the very flowers. Calyx ſmooth. Corollets pale yellow. The flower reſembles that of *Sc. humilis*, from which however it certainly differs very much in having always the ſtem full of leaves. It agrees more nearly with *Sc. purpurea*, but the flowers are very different. Buxbaum's figure, cited by Linneus, appears to agree better with *Sc. humilis* [k].

Native of Portugal, Italy and Siberia.—Cultivated by Mr. Miller in 1759 [l].]

7. Leaves ſhorter than thoſe of the preceding. Stalk taper, and branching at the top. Flowers pale purple. [Deſcribed of blue fleſh-colour by Linneus, and red fleſh-colour by Scopoli. The whole plant is ſmooth. Stem ſimple or branched, ſtriated. Leaves almoſt half a foot in length, graſs-like, but three-ſided and keeled. Scales of the calyx as many as twenty, reddiſh at the tip. Cylinder of anthers pale. Seed ſmooth with the rays of the down of a pale rufous colour [m].

Native of the March of Brandenburgh, Auſtria, Carniola, Barbary and Siberia. Cultivated by Mr. Miller in 1759.]

Digitized by Google

8. This grows a foot and half high. The peduncle immediately under the flower is thicker than it is below, and the lower part of the ſtalk is hairy. The flower is yellow.

[Stem ſcarcely a ſpan high, branched at the baſe and villoſe. Leaves cluſtered, almoſt the length of the ſtem. Flower large. Corolla yellow, purpliſh underneath, the length of the calyx [n]. Down ferruginous, three times as long as the ſeed.—The ſtem is ſometimes ſimple and one-flowered, with the leaves only half its length [o].

Villars diſtinguiſhes it by its being a lower plant than the *hiſpanica*; the leaves aſh-coloured, a little villoſe, and very narrow; the ſtem naked and villoſe at the baſe. It cannot therefore be Barrelier's plant, which is figured leafy from top to bottom [p]. Moriſon has figured this under the name of the *humilis*; and Haller has not well diſtinguiſhed theſe two ſpecies [q].

Native of the South of Europe and Siberia. Cultivated by Mr. Miller in 1759.

9. Leaves channelled. Seeds hairy, white, pappoſe [r]. Leaves entire, ſtrict, ciliate; ſtem rough-haired; peduncles thickened under the flower; calyxes ſhorter than the corolla. Biennial [s].

Native of Apulia and Provence.]

10. This is very like the *laciniata*, except that the ſtalks ſpread on the ground; the indentures on the leaves are more obtuſe, and the tops of the calyxes are woolly.

[Miller has copied theſe characters from Linneus. Vahl informs us, that he has never found the tops of the calyxes to be tomentoſe, but conſtantly whitiſh with a cartilaginous tip, as are the teeth of the leaves. He thus deſcribes the ſpecies.—Root fuſiform. Stem ſimple or branched, a foot high or more, round, ſmooth as is the whole plant, ſtriated, purpliſh. Root-leaves numerous, ſtem-leaves few, alternately unequally toothed; the lower ones towards the middle of the leaf tooth-pinnatifid, all the teeth terminated by a whitiſh cartilaginous point. Peduncles ſometimes branched, few, having at the baſe and in the middle a ſagittate entire leaf. Pedicels ſcaly one-flowered. Flowers ſmall. Calyx-leaves ſmooth; the outer ovate, the inner lanceolate: all obtuſe, terminated by a cartilaginous ſcale.

According to Villars, the ſtem is commonly ſpread on the ground, or only riſing a little at the end, not upright as Vahl deſcribes it; the lower leaves wider, the upper lyrate or pinnatifid, with the diviſions lanceolate; peduncles axillary, terminated by a ſmall yellow flower; ſcales of the calyx a little hooked or ending in a ſpinule, as in the *laciniata*; but this character is inconſtant. The procumbency or inclination of the ſtems is the only ſenſible character in Dauphiné.

D'Aſſo ſays, it is ſcarcely a diſtinct ſpecies from the *laciniata*, unleſs the nap of the calyx be a ſufficient mark; for it has the ſame appearance, and the diviſion of the leaves is the ſame.

Villars remarks, that Boccone's figure, cited by Linneus (Vahl, and D'Aſſo) does not repreſent this plant.—Here therefore is ſome confuſion, and perhaps two ſpecies confounded, or a variety of *laciniata* mixed with this ſpecies.

Native of Spain and the South of France. Vahl found it on the coaſt of Africa. Cultivated by Mr. Miller before 1729. It is a biennial plant, and flowers in june and july [t].

11. Stem upright, herbaceous, a foot high, the thickneſs of a gooſe quill, ſtriated, rugged, ſomewhat branched: branches of the ſame ſtructure with the ſtem, ſpreading. Leaves ſmooth, next the root abundant, ending in the petiole, lyrate-pinnatifid; ſegments alternate, roundiſh or oblong, often irregular, the end one thrice or four times as large as the reſt: thoſe at the top of the ſtem remote, few, pinnatifid; ſegments linear-lanceolate, rugged at the edge. Peduncles terminating, ſolitary, three or four inches long, ſomewhat grooved, one-flowered, having a ſmall awl-ſhaped entire leaf at top. Calyx the ſame ſize as in *Sc. humilis*: the leaflets ovate attenuated, keeled, moſtly ſmooth, very tomentoſe and whitiſh at the tip, ſometimes naked. Corolla ſulphur-coloured. Down feathered [u].

Vahl remarks, that this ſpecies agrees with Barrelier's figure, cited under *reſedifolia*, but by no means with Boccone's, which agrees with that, except in being too ſmall, and in the tips of the calyx leaves. Both ſeem to be different from Gouan's *reſedifolia*.

S. calcitrapifolia is not a variety of *laciniata*; for the ſegments of the leaves are always linear, not oblong, and the whole habit of the plant is different.

Native of the kingdom of Tunis in Africa [x].]

12. This riſes with a ſmooth branching ſtalk two feet high, and has leaves like thoſe of Buck's-horn Plantain, but larger. Flowers yellow, upon long naked peduncles, at the end of the branches.

[Root biennial. Primary root-leaves entire, ſpatulate, on long membranaceous petioles: the other leaves ſinuate, pinnatifid, with three or four lanceolate-linear ſegments on each ſide; the end one longer. Stem-leaves ſmaller, ſinuate or entire, ſeſſile. Stem ſtriated, branched at the baſe; branches naked, longer than the leaves, one-flowered. Scales of the calyx lanceolate, acute, membranaceous, the outer ones having a toothlet at the end, the lower ones bent back. Corollas longer than the calyx, yellow [y].

Receptacle, according to Gærtner, ſlightly convex, papilloſe with minute tubercles. Seeds long, from an ovate ſtriated peduncle hollow within and containing a filiform umbilical cord, lengthened out into a ſtraight, compreſſed-four-cornered, ſtriated column, narrower than its peduncle but twice its length, and filled with the nucleus.

According to Monſ. Villars, it reſembles the *reſedifolia*, but the ſtem is upright ſtraight and branched; the leaves are alſo narrower, and the diviſions are not quite ſo wide; the flowers are ſmall, in an angular calyx, the ſcales of which are terminated by a cottony button. After all, it ſeems doubtful whether this and the *reſedifolia* be really different; they appear at firſt view to be very diſtinct, but they are both ſubject to vary. They have each the character of the other in the ſcales of the calyx. The width and form of the leaves vary alſo. The ſtems ſeem to be more conſtant; but the diſpoſition to procumbency in the *reſedifolia* ſometimes changes a little, and the ſtems are raiſed enough to approach to this ſpecies. Haller, Gouan, Gerard, &c. do not appear to have diſtinguiſhed them [z].

Native of Germany, Switzerland, Auſtria, the South of France, Italy and Spain. Mr. Miller cultivated it before 1729; but Parkinſon had it in 1640 [a].

13. Root perennial, fuſiform, in thickneſs from that of the little finger to the thumb. Stem a finger or hand high, upright, ſtriated, tomentoſe hoary, naked or having a few (one to three) leaves at bottom, a little thickened under the flower. Root-leaves abundant, pubeſcent, (but with age becoming naked above,) acute, pinnatifid, wider in the middle: ſegments linear, acute, unequal, rather remote, quite entire or laciniated. Petioles channelled, ſtriated, widening at the baſe. Flower terminating, ſolitary, the ſame ſize as in *Sc. hiſpanica*. Calyx ovate-oblong, with the ſcales often tomentoſe at the edge; the outer ovate, the inner lanceolate, longer, membranaceous. Corolla longer by half than the calyx, ſulphur-coloured. Anthers brown or duſky purple. Seeds columnar, rugged with raiſed muricated lines. Down ſeſſile, feathered, or compoſed of many, unequal, cobwebbed briſtles. Receptacle naked, convex.—Native of the mountains of Barbary [b].

14. Leaves deeply toothed, almoſt like thoſe of Dandelion, with the edge toothletted, ſmooth. Stems ſhort, leafy. Lower calyx-ſcales, eſpecially at the ſides, widely membranaceous along the edge. Corolla yellow, the ſame ſize as in *Sc. humilis*.—Found in the Eaſt by Haſſelquiſt [c].

[n] Linn. ſpec. [o] Scopoli. [p] Haller. [q] Villars. [r] Linn. mant. [s] Gerard. [t] Hort. kew. [u] Vahl. [x] Idem. [y] Gerard. [z] Villars. [a] Hort. kew. [b] Desfont. and Vahl. [c] Linn. ſpec.

15. The

Digitized by Google

15. The root of this is perennial, fuſiform, and white, and ſcarcely the thickneſs of one's little finger: the radical leaves are numerous, ſubruncinate, and ſcattered in a circular direction: they are obtuſe, laciniated, and edged with fine hairs: ſtalk ſmooth, ſtriated, leafleſs, branched, fiſtulous, and about a foot and half high: peduncles elongated, one-flowered: calycine ſcales greeniſh, and edged with a whitiſh membranaceous margin: flowers deep yellow [d].

Native of Bohemia; flowering from july to the end of auguſt.

16. Stem upright, ſmooth, branched. Leaves glaucous, ſmooth, ſomewhat fleſhy, unequally toothed and runcinate, rounded on both ſides at the baſe. Peduncles inflated at top, one-flowered, clothed with little ovate ſcales. Calyx ventricoſe; ſcales ovoid, looſiſh, acuminate, membranaceous at the edge. Corollets villoſe at bottom. Seeds truncate, four-cornered. Down villoſe, whitiſh, ſimple [e]. Hence Desfontaines makes this and the *picroides* of another genus, *picridium*. According to Hermann it is a *Chondrilla*; in Tournefort it is a *Sonchus*; in Vaillant a *Crepis*.—Linneus remarks, that though the pappus be ſimple, yet the calyx-ſcales are ſcarioſe at the edge.

It is an annual plant, native of Tangier on the Barbary coaſt; in clefts of rocks. Cultivated in the Chelſea garden in 1713 [f]: but not mentioned by Mr. Miller [g].

Mr. Curtis obſerves, that in the middle of ſummer, a hot unclouded ſun, which is favourable to the expanſion of moſt flowers in the claſs Syngeneſia, is too powerful for theſe, which appear to the greateſt advantage in warm hazy weather.

17. Stems ſeveral erect, round, ſmooth, ſtriated below, branched from the baſe: branches dichotomous, rigid. Moſt of the leaves radical, petioled, a long ſpan in length, ſmooth: ſegments lanceolate, tooth-angular, outwardly larger, ſubciliate with minute whitiſh toothlets. Stem-leaves under the two firſt ramifications, ſeſſile, of the ſame ſtructure with the others: then ſmall lanceolate leaves, gradually ſmaller, ovate, quite entire, under each branch. Flowers terminating, ſolitary, on ſcaly peduncles not thickened under the flower: ſcales a little under the flowers crowded, ovate, membranaceous at the edge, ending in the calyx. Calyx cylindrical, very ſmooth: outer leaflets ovate, with a wide membranaceous margin, looſe; inner leaflets or ſcales linear. Corolla yellow, longer than the calyx. Pappus hairy or ſimple, ſeſſile. Allied to *Sc. picroides*, yet different.—Found by Vahl in the kingdom of Tunis [h].

18. The outer ſeeds are curved in and crenulate; the pappus is ſimple and ſeſſile: this plant therefore is intermediate between *Scorzonera* and *Sonchus* [i]. Hence it is a *Sonchus* in moſt of the old authors; and Desfontaines forms a new genus for this and other ſpecies reſembling it. He ſays, that it varies with entire, laciniate, and runcinate leaves.

It is an annual plant, native of the South of France, and of Barbary.

Monſ. Richard introduced it here, in 1773. It flowers from june to auguſt [k].

John Bauhin has it twice; the deſcription in p. 1018, but the true figure in p. 1021 [l].

19. Stem ſuffruticoſe, erect, weak, three feet high, branched. Leaves toothletted, thick, ſmooth. Flowers pale yellow, on ſubumbelled peduncles. Calyx oblong. Receptable naked. Down feathered.

Native of the continent of eaſtern Africa, near Mozambique [m].]

PROPAGATION AND CULTURE.

The firſt ſort only is cultivated for the uſe of its roots, the others are preſerved in botanic gardens for variety, but are ſeldom admitted into other gardens.

Theſe plants may be propagated by ſowing their ſeeds in the beginning of april, upon a ſpot of light freſh ſoil. The beſt method of ſowing them is, to draw ſhallow furrows by a line about a foot aſunder, into which you ſhould ſcatter the ſeeds, thinly covering them over about half an inch thick with the ſame light earth; and when the plants are come up, they ſhould be thinned where they are too cloſe in the rows, leaving them at leaſt ſix inches aſunder; and at the ſame time, you ſhould hoe down all the weeds to deſtroy them; and this muſt be repeated as often as is neceſſary, for if the weeds are permitted to grow among the plants, they will draw them up weak.

There are many people who ſow their ſeeds promiſcuouſly in a bed, and afterwards tranſplant them out the diſtance they would have them grow; but this is not ſo well as the former method, becauſe their roots commonly ſhoot downright, which in being tranſplanted, are often broken, ſo that they never will make ſuch fair roots as thoſe which remain in the ſame place where they are ſown; for when the extreme part of the root is broken, it never extends itſelf in length afterwards, but only ſhoots into many forked ſmall roots, which are not near ſo valuable as thoſe which are large and ſtraight. Theſe roots may be taken up when the leaves begin to decay, at which time they have done growing, though they may remain in the ground until ſpring, and may be taken up as they are uſed; but thoſe which remain in the ground till march, will ſhoot up their flower-ſtems, after which they are not ſo good, being ſticky and ſtrong.

If you intend to ſave ſeeds of theſe plants, you ſhould let a parcel of the beſt remain in the places where they grew; and when their ſtems are grown to their height, they ſhould be ſupported with ſtakes, to prevent their falling to the ground, or breaking. In june they will flower, and about the beginning of auguſt their ſeeds will ripen, when they ſhould be gathered, and preſerved dry till the ſpring following for uſe.

SCROPHULARIA. (*From its ſuppoſed uſe in the cure of the Scrofula.*)

Lin. gen. n. 756. *Reich. n.* 814. *Schreb. n.* 1014. *Tournef. t.* 74. *Juſſ.* 119. *Gærtn. t.* 53.

Claſſ. 14. 2. Didynamia Angioſpermia.

Nat. order of *Perſonatæ*. *Scrophulariæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-cleft, permanent: *ſegments* ſhorter than the corolla, rounded.

COR. one-petalled, unequal: *tube* globular, larger, inflated: *border* five-parted, very ſmall: *ſegments* the two upper larger, erect; two lateral, ſpreading a little; one loweſt, bent back.

STAM. *Filaments* four, linear, declining, length of the corolla; of which two are later. *Anthers* twin.

PIST. *Germ* ovate. *Style* ſimple, ſituation and length of the ſtamens. *Stigma* ſimple.

PER. *Capſule* roundiſh, acuminate, two-celled, two-valved: *partition* folded, conſtructed of the margins of the valves bent in; opening at the top.

SEEDS very many, ſmall. *Receptacle* roundiſh, inſinuating itſelf into each cell.

OBS. *In the throat of the corolla under the upper ſegment of the border is found a ſmall ſegment, reſembling a little lip, which is not common to all the ſpecies.*

The corolla in this genus ſhould be conſidered as reſupine or turned upſide down: the upper lip ſmaller recurved, to which the ſtamens are bent down, rounded; the lateral ſegments crenate, rounded, equal to the upper one; lower lip larger, patulous, two-parted; the middle one very ſmall in front.

The partition, when the capſule is ripe, has an oval hole through it. G.

ESSENTIAL CHARACTER.

Cal. five-cleft. *Cor.* ſubglobular, reſupine. *Capſ.* two-celled.

Desfont. atlant. 55.
Stem four-cornered erect hiſpid, leaves pinnate doubly-crenate, terminating lobe cordate very large, raceme compound leafleſs.]

DESCRIPTIONS, &c.

1. Root perennial, fibrous. Stalks four-cornered. Flowers in bunches on the upper part of the ſtalk, like thoſe of the next ſpecies, but of an herbaceous colour.

[It very much reſembles our common knobby-rooted Figwort, but is double the height. Leaves cordate at the baſe, but not three-nerved or cut out to the very nerves. Petioles connected on each ſide by a very ſmall beard [a]. The flowers are diſpoſed more thinly and ſcatteringly than in our common ſort [b].

Native of North America: Miller ſays Maryland; Linneus Virginia. Ray names it *marilandica*; and ſays it was found, and brought from America by Krieg a German. Cultivated in 1759, by Mr. Miller; who having omitted in his eighth edition, n. 16. of his ſeventh; has numbered this 16, and deſcribed it as the 17th ſpecies in his eighth folio edition. This miſtake is rectified in his ſixth quarto edition.

2. Root tuberous, granulate, (or compoſed of many whitiſh knobs.) Stem three feet high, erect, ſimple, acutely quadrangular, ſmooth, leafy. Leaves oppoſite, petioled, ſmooth, acutely ſerrate, veined and at the baſe by the lateral veins cut out and as it were three-nerved. Raceme terminating, erect, with the peduncles oppoſite, dichotomous, having a pair of lanceolate acuminate little bractes. Flowers dark blood-red. Capſules ovate, acute [c].—To this Dr. Withering adds, the upper leaves are nearly ſeſſile and lanceolate; the peduncles cylindrical, with ſhort pellucid hairs terminated by globules; calyx toothed and membranaceous at the end; baſe of the corolla filled with a honey-like liquor; upper ſegments purple, the reſt pale green: the little heart-ſhaped ſegment within the baſe of the two upper ſegments ſeems to deſerve the name of nectary. The capſule ſometimes has three or four cells.

Native of Europe, in woods and hedges; flowering in july.

It has the name *Figwort*, and formerly *Kernelwort*, from its knobbed roots: *Brownwort*, from the brown tinge of the leaves, &c.

This plant is hardly known in modern practice; but the rank ſmell, like Elder, and bitter taſte of the leaves, ſeem to indicate ſome active properties. Swine that have the ſcab are cured by waſhing them with a decoction of the leaves. Waſps reſort greatly to the flowers. Goats eat the plant; but cows, horſes, ſheep and ſwine refuſe it [d].

There are ſome varieties. Pontedera mentions one with the leaves in threes, inſtead of two oppoſite in pairs. Ray has it without any of the brown colour uſual in this plant; but with the ſtems, leaves and flowers all green: found near Cumner by Bobart.—Parkinſon figures a third, under the name of *S. major altera elegans*, which, like the firſt, has ſometimes more than two leaves at a joint, eſpecially the lowermoſt.

3. Root perennial, fibrous. Stem from three to five feet in height, upright, branched, ſmooth, winged at the corners: branches leafy, like the ſtem. Leaves oppoſite, petioled, cordate-ovate, obtuſe, ſerrate, ſmooth, veined, running down at the baſe into the petiole.

Mr. Curtis remarks that they have ſometimes little appendages: and Dr. Withering, that the upper leaves are ovate. Flowers in an erect terminating raceme, commonly ſolitary: or, according to Mr. Curtis, in a panicle-like ſpike, with the branches oppoſite, trichotomous, ſupported by a pointed bracte; the lateral peduncles have often ſeveral flowers with a little bracte to each, and are ſomewhat viſcid; the middle one is ſolitary. Corolla of a deep blood-red colour. Capſule roundiſh, acuminate [e]; two-grooved, ſmooth, bipartile: receptacle ovate-oblong, ſpongy, faſtened to the partition on each ſide, when ripe contracted into a thick tubercle, faſtened to the baſe of the oval hole. Seeds ovate-globular, becoming by age grooved and tranſverſely wrinkled ſo as to appear latticed, dark brown [f].

Native of Europe, by the ſides of rivers, ponds and wet ditches; flowering from june to ſeptember.

The name of *Water Betony* has been given to this plant, from the ſimilitude of its leaves to thoſe of Wood Betony. It was formerly known by the name of *Brown-wort*, as well as the preceding; and in Yorkſhire, ſays Gerarde, it is called *Biſhop leaves*.

The leaves of this ſpecies are recommended medicinally for the ſame purpoſes as thoſe of the preceding: in taſte and ſmell they are ſimilar, but weaker. Monſ. Marchant having reported, in the Memoires of the French Academy, that this plant is the ſame with the *Iquetaia* of the Braſilians, celebrated as a corrector of the ill flavour of Sena, the Edinburgh College, in their common infuſion of that drug, directed two thirds of its weight of Water-Figwort leaves to be joined; but as they have ſince diſcarded this ingredient, we may preſume that it was not found to be of much uſe.

The diſagreeable ſmell which attends this plant when bruiſed, makes it rejected by cattle in general, nevertheleſs both leaves and flowers are much reſorted to by different kinds of inſects. Bees and waſps collect much honey from the flowers, which continue a long time [g].]

There is a variety of this with variegated leaves.

4. [This has the ſtature of *S. nodoſa*. Stem four-cornered, by no means hairy, brachiate. Leaves doubly-ſerrate, obtuſe every where, opaque, naked, having two ovate acceſſory leaflets at the baſe, ſo that they are in a manner ternate; on the ſmaller branches the leaves are ſimple. Corollas of a more duſky purple colour, with the lip which is rolled back of a greeniſh livid colour [h]. The ſynonyms of Barrelier and Tournefort, given in the Species Plantarum, do not belong to this plant, but to *betonicifolia*, n. 9.

It has the appearance of *S. nodoſa*. Stem upright, ſeldom divided, ſmooth. Leaves petioled, wrinkled, oblong; teeth unequal, ovate, bluntiſh; the lower

[a] Linn. ſpec. [b] Ray. [c] Smith. [d] Withering. [e] Smith [f] Gærtner. [g] Curtis. [h] Linn. ſpec.

Digitized by Google

ones pinnate at the base, with two or four pinnules, the extreme lobe larger, cordate or ovate; the upper ones cordate, simple. Flowers in leafless racemes, whorled as it were. Peduncles in pairs, opposite, short, dichotomous. Bractes small, linear, shorter than the calyx, from the base of each pedicel. Segments of the calyx rounded, pressed close, membranaceous at the edge. Corolla purple, spreading, very like that of *S. nodosa*, but a little less: lamella of the palate orbicular. Capsule pear-shaped, acute, smooth, with a longitudinal furrow on each side. Seeds, black, oblong, dotted and wrinkled, fastened to the central receptacle [z].

It seems to be the *sulphurea* of Miller, *n.* 3. which he describes as having] stronger, taller and greener stalks than the *aquatica*; the leaves generally with small appendages at their base; the flowers greener, and growing thinner upon the stalks. [He supposes it to be the *St. aquatica flore sulphureo* of Micheli, and hence names it *sulphurea*.

Native of Spain, Italy and Algiers. Introduced in 1772, by Monf. Richard [y]: unless it is Miller's *sulphurea*, which he cultivated in 1759.

5. Stem upright, quite simple, a cubit high, four-cornered from four decurrent lines. Leaves two inches long, very smooth, shining, veined, on a petiole shorter than the leaf. Raceme erect, strict, a span long: peduncles alternate, distant, twice or thrice dichotomous; pedicels divaricating, one-flowered, solitary in the forkings. Bractes at the base of the peduncles and pedicels, linear, short. Segments of the calyx rounded, membranaceous with a white edge, shorter by half than the corolla; which is of the same size as that of *S. nodosa*; with the upper lip purplish, and the lower greenish yellow. Capsule longer than the calyx.

Native of Barbary, in the mountains near Zowan in Tunis [z].

According to Desfontaines, this is the same with the *trifoliata* of Linneus; which see under n. 15.

6. Stem four-cornered, hairy. Leaves cordate-oblong, acute, veined, very soft beneath, cut out and three-nerved at the base. Peduncles of the raceme decompounded, the upper ones alternate. Flowers paler. Calyx pubescent. Capsule smooth, roundish, acuminate [a].

Desfontaines distinguishes it from *auriculata*, by the flowers being panicled; the peduncles filiform, longer, patulous; the leaves not pinnate at the base, scarcely pubescent, with the teeth sharper.

Native of Portugal, Italy, Tunis in Africa, Siberia, and Britain. Discovered in the Island of Jersey, between the Port and St. Hilary, by Sherard; and since by Mr. Edward Lhwyd and others, near the sea shore about St. Ives in Cornwall [b].]

Mr. Miller says, the stalks rise near four feet high, branching out on every side; that the leaves on the upper part of the stalks are alternate; that the flowers are produced in bunches at the axils, each pedicel supporting two flowers, which are small, of a brown colour, and appear in june.

He has another species, (n. 6.) which he names *italica*, and is a native of Sicily. The flowers are disposed in compound spikes, upon long foot-stalks from the axils, having generally two narrow leaves at the base; but the flowers terminate the stalks, as in *nodosa* and *aquatica*. [He quotes the same specific character as in the *Scorodonia* from Linneus, with a synonym from *Hort. Cathol.*—Sc. nemorensis folio urticæ rugoso, flore atro-punicante.—It is probably a variety of the *Scorodonia*.

7. Root consisting of thick fibres of about a finger's length: stem sometimes single, and sometimes multiple; upright, and about a quill's thickness at the base: branches spreading, about a span long, leaves ovate-oblong, doubly serrate, cordate, veiny, rather wrinkled, opposite, and horizontal: flowers collected in a terminal raceme on the stem and branches: corolla whitish externally, and of a deep green internally: border larger than usual in this genus, and with a very long obcordate upper segment.—Native of the Altaic mountains [c].

8. This is a biennial plant, native of the Canary Islands, where it was found by Masson, and introduced in 1779. It flowers in april and may [d].

9. Stem two feet high, erect, four-cornered, subpubescent, purplish at the base. Leaves opposite, petioled, subcordate, oblong, being three times as long as they are wide, wrinkled, subpubescent beneath, sharply toothed, with the teeth acuminate and quite entire, (therefore very like those of Ebulus or dwarf Elder,) deeper at the base. Petioles shorter than the leaves. Panicle terminating somewhat leafy. Corollas of a dull purple colour, with a greenish lip. Anthers very yellow.

Native of Portugal [e]: of Spain, according to the Kew catalogue; of Sicily, as Miller affirms; and Allione had it from the county of Nice. It was cultivated by Miller so far back as the year 1739 [f].]

He names it *cordata*, and says that the stalks rise near four feet high and have sharp angles; that the leaves are arrow-pointed, heart-shaped, and sharply serrate; that the flowers grow in loose terminating bunches, are in shape like those of *auriculata*, but of a dark-red colour.

[10. Stem quadrangular, herbaceous; with opposite branches. Leaves opposite, petioled, ovate or a little oblong, even, equally serrate, longer than the petioles. Racemes terminating, solitary. Bractes leafy, but smaller, commonly quite entire, remote; the lower opposite, the upper alternate. Peduncles leafless, longer than the flower. Corollas ovate, of the same size as in *S. sambucina*.—Found in New Granada, by Mutis [g].]

11. Root perennial, creeping. The stalks rise two feet and a half high; their lower parts are closely set with lanceolate leaves, which are sharply serrate, and cut at bottom. At the upper part are compound bunches of small brown flowers, which appear in may; and are succeeded by small roundish capsules.—Native of the Levant.

[Linneus remarks, that the stem-leaves are sometimes in fours as well as threes; and that the raceme is composed of three or four dichotomous peduncles.—It was cultivated in the Chelsea garden in 1712; and flowers in july and august, according to the Kew catalogue.

12. Stem perennial, (or becoming woody,) four-cornered, acute-angled, brachiate below. Leaves ovate, toothed, shining, smooth, small, opposite: the lower obovate; the upper oblong. Raceme terminating, leafy, with quite entire bractes, and opposite trifid peduncles, the length of the bractes. Corollas small, very dark purple, with the lateral segments white, and the lowest segment very small [h].

Native of Portugal; and also, as Monf. Desfontaines informs us, of the kingdom of Tunis, near Elhammah.—It was cultivated in 1768, by Mr. Miller [i]: and is the 17th species of his Dictionary, but described as the 16th.

13. Root fibrous, biennial. Stem hairy, about two feet high, square or five-cornered; and in the latter case the leaves grow three together, as Linneus in his manuscripts defines them; but they are full as often opposite: they are pointed, sharply and doubly serrate, veined, most hairy beneath, and petioled. Peduncle the length of the leaves, bearing many flowers, in clusters. Calyx hairy. Corolla inflated, yellow, contracted at the mouth. Capsule ovate, acute [k].

Dr. Smith has a curious remark on the affinity between this plant and the pretty Peruvian genus of *Calceolaria*, one species of which, the *pinnata*, is now frequent in our gardens; the fruit and seeds, the calyx, the habit and hue of the whole plant strikingly agree: and there is another species, *Calc. ovata*, between which and this *Scrophularia* the conformity is still greater; so that a somewhat different form of corolla, and having only two stamens, are

[y] Desfontaines. [z] Hort. kew. [a] Vahl. [b] Smith. [c] Ray syn. [d] Murray. [e] Hort. kew. [f] Hort. kew. [g] Mutis. [h] Linn. mant. [i] Hort. kew. [k] Linn. mant. [l] Smith.

Digitized by Google

the only generic diſtinctions of that *Calceolaria* from this *Scrophularia*. In every thing elſe they are much nearer akin than this plant and the other ſpecies of the ſame genus [l].

Native of Italy, the South of France, Switzerland, Auſtria, Denmark, England, and Wales. About Bury in Suffolk by Sir Thomas Gery Cullum, Bart. who aſſures me that it grows alſo at Hemſted in Eſſex, where our famous phyſician Harvey lies buried. Mr. Woodward has alſo obſerved it at Fornham near Bury: Archdeacon Peirſon about Newburgh in Yorkſhire. Dr. Withering likewiſe mentions that it grows at Gloddaeth in Caernarvonſhire. But it was firſt diſcovered by Mr. Alexander Smith, ſurgeon at Croydon, in april 1759, near Mitcham in Surry, by the common field in the way to Merton [m]. There Mr. Hudſon afterwards, and Mr. Lyſons lately have found it.

Our four Britiſh ſpecies are thus well diſtinguiſhed by Mr. Woodward:—*Scrophularia nodoſa* has the leaves cordate, acute, and acutely ſerrate: the flowers on dichotomous branches, with a pair of lanceolate, acuminate bractes.—*Scroph. aquatica* has the leaves cordate-ovate and crenate: the flowers in a naked branched panicle, with the lower branches oppoſite, the upper alternate, dichotomous; and a pair of ſubulate bractes at the baſe of each branch.—*Scr. Scorodonia* has the leaves downy; the upper ones terminating in an awn, as do the ſerratures; and beneath each branching of the peduncles a pair of awl-ſhaped bractes. *Sc. vernalis* has the ſtem, leaves and peduncles hairy; the leaves doubly ſerrate; the primary peduncles longer than the leaves, the ſecondary ſhort; and beneath theſe a pair of lanceolate hairy bractes [n].

14. This differs from the preceding in having the ſtem and leaves ſmooth, with the flowers ſmaller and red. It was found in the iſlands of Madeira and Teneriffe, by Mr. Fr. Maſſon, and was introduced in 1778. It flowers in may and june; and is an annual plant [o].

15. Stem ſimple or ſparingly branched, erect, ſmooth, four-cornered, ſtriated. Leaves cordate, ſmooth and even, ſhining, veined, obtuſe, unequally and obtuſely double toothed, petioled; the lower ones often eared at the baſe. Raceme interrupted. Peduncles alternate. Flowers pedicelled, in racemelets. Bractes linear, ſome longer, ſome ſhorter than the pedicels. Segments of the calyx ovate, obtuſe, membranaceous at the edge. Corolla as in *aquatica*, purple. Capſule pear-ſhaped, longer than the calyx, even, mucronate [p]. According to Plukenet, the flower is beautifully variegated with red and yellow. Boccone ſays it is pale yellow; and Miller, that it is bright red with a greeniſh bottom.

Native of Corſica and Africa, on the borders of fields, and on the ſea-coaſt. Linneus marks it as biennial; Miller and Desfontaines as perennial.

16. Stem erect, four-cornered from the decurrent petioles. Leaves pinnate, with five or ſeven leaflets, (beſides the ſmaller ones placed between them) cordate, wrinkled, ſmooth above, ſerrate, with the end one larger. Raceme terminating, compoſed of very ſhort, ſubdichotomous, axillary peduncles in pairs. Flowers large, purple with the lower lip greeniſh [q].]

This reſembles the preceding, but the ſtalks are larger, riſe higher, and are hairy. The leaves are much longer, and have four appendages, are irregularly ſerrate, and run out into longer points. The flowers, which are in compound axillary bunches, are larger, and have a greater mixture of green.

Native of Portugal, [and Spain. Cultivated before 1629, by Parkinſon. It flowers from july to ſeptember; and is perennial [r].

17. Root annual. Stem four-cornered. Branches numerous, panicled, dichotomous. Leaves ſmooth; the lower gaſhed, the upper pinnate or pinnatifid, with the diviſions remote, widiſh, linear, ſimple or ſublobed, acute. Flowers in panicles. Corolla ſmall, deep purple; without any lamella in the palate [s].

[l] Engl. bot. [m] Plantæ Cantabr. app. [n] Mſs. [o] Hort. kew. [p] Desfontaines. [q] Linn. ſpec. [r] Hort. kew. [s] Desfontaines.

Linneus remarks, that the peduncles are bifid; and the flowers ſeſſile, the firſt being axillary, the reſt alternate.]

Root compoſed of a few thick fleſhy fibres. Stalks ſlender, two feet high. Lower leaves compoſed of ſeveral pinnæ or lobes which are ſharply ſerrate; but thoſe on the ſtalks are entire: on the lower part of the ſtalk they are oppoſite, but towards the top alternate and ſmall. Flowers in axillary bunches; ſmall, and of a dark purple colour with a mixture of green. Seed-veſſels ſmall and roundiſh.

Native of the South of Europe, and of Barbary. Cultivated in 1683, by Mr. James Sutherland. It flowers from june to auguſt [t].—Linneus and Desfontaines mark it as annual; the Kew catalogue as perennial.

18. Stem herbaceous, erect, from two to three feet in height, ſimple, four-cornered, with four decurrent lines, ſmooth, as is the whole plant. Leaves petioled, oppoſite, a hand in length; the lower pinnate; the upper ternate-pinnate. Leaflets petioled, alternate, diſtant, about five, the lower one ſmaller, the end one three-parted, all the parts ſeſſile, oblong or lanceolate, unequally tooth-gaſhed, with the teeth blunt. Peduncles axillary, oppoſite, four-cornered, three-flowered. Flowers pedicelled. Bractes three or four, linear-lanceolate, length of the pedicels. Segments of the calyx roundiſh, membranaceous at the edge. Corolla nearly of the ſame ſize as in *S. ſambucifolia*, purpliſh green. Capſule ovate, bigger than a pea [u].

Native of Barbary. Introduced in 1786, by Monſ. Thouin. It flowers in july and auguſt, and is perennial [x].

19. Stem round, ſtraight, green. Leaves reſembling thoſe of *S. canina*, but ſomewhat fleſhy. Raceme rigid, erect. Corollas pale, with the upper lip red [y]. Leaflets thickiſh, gaſhed, ſhining. Palate of the corolla furniſhed with a little orbicular lamella [z].

Miller, following Tournefort, makes the *Scr. foliis filicis*, &c. of Caſp. Bauhin, a diſtinct ſpecies, under the name of *filicifolia*. This he deſcribes as having] a root compoſed of fleſhy fibres; the lower leaves broad and jagged, not much unlike thoſe of the Indian Scabious; the ſtalk near three feet high, four-cornered, green and ſmooth, with pinnate leaves on very long foot-ſtalks; they are compoſed of two or three pairs of ſmall leaflets terminated by a large one, acutely indented, and ending in ſharp points. Flowers in terminating ſlender bunches, placed ſcatteringly, ſmall, of a purpliſh colour at their rims and edged with white. Seed-veſſels ſmall and roundiſh.—Native of Crete.

He deſcribes the *lucida* as a biennial plant, with ſtalks fifteen inches high, thick, ſmooth, and having ſcarcely any corners; leaves pinnate, narrow, of a lucid green, thick, ſucculent, and divided into many leaflets, which are again divided (bipinnate;) flowers in looſe bunches on the ſides and at the top of the ſtalk, of a dark brown colour with a mixture of green; capſules roundiſh, pretty large, filled with angular dark-coloured ſeeds.—Native of the kingdom of Naples, where it is frequent upon rocks and old ſtone walls.

[Native of the Levant, the county of Nice, and Barbary. Cultivated before 1680, by Robert Moriſon, M.D. [a]]

20. Root biennial. Stalk two feet high. Leaves ovate, acute, ſerrate, ſeſſile; at the bottom and top of the ſtalk placed by pairs, but in the middle there are three or four at each joint; all of a pale green colour. The flowers are produced at the top of the ſtalk in roundiſh bunches; they are about the ſame ſize with thoſe of the *nodoſa*, but of a fine ſcarlet colour.—Diſcovered by Dr. Houſtoun, at La Vera Cruz in New Spain.

21. Leaves ending in acute points, ſerrate, of a lucid green, and on the upper part of the ſtalk alternate. The peduncles each ſuſtain two or three flowers, which are of a dark-red or purple colour. They appear in may and june, and the ſeeds ripen in july and

[t] Hort. kew. [u] Vahl. [x] Hort. kew. [y] Linn. [z] Desfontaines. [a] Hort. kew.

auguſt,

Digitized by Google

auguſt, after which the plants die. [According to Linneus and the Kew catalogue, the root is annual.—Native of Italy. Cultivated in 1683, by Mr. James Sutherland [b].

Linneus remarks, that the ſtem is dark-purple, and has four, five or ſix acute angles; that the peduncles have from two to five flowers; and that the corolla is purple [c].

22. Stem ſimple or but ſparingly branched, firm, hiſpid with ſhort and very numerous hairs. Leaves oppoſite, on ſhort petioles, villoſe, ſoft, aſh-coloured: pinnules ovate, few, often-cut out in front, ſubpetioled, with the terminating leaflets ſometimes ſublobed. Raceme interrupted: racemelets oppoſite or alternate, hirſute, branched. Flowers pedicelled, Bractes linear, longer or ſhorter than the pedicel. Calyx permanent, ſmooth, five-parted: ſegments roundiſh, preſſed cloſe, ſurrounded by a membranaceous margin. Corolla ſpreading, the ſame ſize as in *S. noëſa:* tube ſhort, globular; upper lip longer, horizontal, two-lobed, with the lobes rounded, the lower three-lobed; lamella of the palate orbicular. Capſule even, very ſmooth, pear-ſhaped, mucronate. Seeds brown, oblong, obtuſe, dotted and wrinkled, faſtened to a central fleſhy receptacle.

Native of mount Atlas near Tlemſen, in the clefts of the rocks [d].]

PROPAGATION AND CULTURE.

Theſe plants are propagated by ſeeds, which if ſown in the ſpring, the plants ſeldom riſe the ſame ſeaſon. Some of them may come up in autumn, and others the ſpring following; but if they are ſown in autumn, ſoon after they are ripe, the plants will come up the ſpring following. Theſe ſeeds may be moſt of them ſown in the place where the plants are to remain, for the plants are in general all of them hardy enough to bear the cold of our ordinary winters in the open air (except the laſt ſort, which is tender;) therefore when the plants come up, they will require no other care but to thin them where they are too cloſe, and keep them clear from weeds. The ſecond year the plants will flower and produce ripe ſeeds; after which thoſe ſorts which are biennial will die, but the others will continue ſome years.

The 15th and 16th ſorts being ornamental plants, may be allowed a place in the pleaſure-garden, where, when the plants are ſtrong, they will make a good appearance during their continuance in flower, which is generally two months, unleſs the ſeaſon prove very hot and dry. The roots of theſe ſorts will abide many years, unleſs by a very ſevere winter they are deſtroyed; therefore it will be proper to put ſome of theſe plants in pots, which may be ſheltered under a common frame in winter; but, as young plants flower ſtronger than the old ones, there ſhould be a ſucceſſion of them annually propagated by ſeeds.

The other ſorts are proper furniture for botanic gardens, but are ſeldom cultivated in any other. The 17th and 19th ſorts ſhould have a dry ſoil, for as they naturally grow upon rocks and old walls, if they are in good ground, the plants will grow vigorous in ſummer, and thereby will be ſo replete with moiſture, as that they are often killed by ordinary froſts, or rot with wet in winter; whereas in a poor dry ſoil, they are ſeldom injured by the cold in England.

The 20th is too tender to live through the winter in the open air in this country, but the ſeeds ſhould be ſown in pots in autumn, which may be ſheltered under a common frame in winter, and in the ſpring plunged into a moderate hot-bed, which will bring them up. When theſe are fit to remove, as many of them as are required ſhould be planted into ſeparate ſmall pots, and plunged into a very moderate hot-bed, ſhading them from the ſun till they have taken new root; after which they muſt be gradually hardened to bear the open air whereinto they may be removed at the end of June, placing them in a ſheltered ſituation, where they may remain till ſeptember, when they ſhould be removed into ſhelter before any morning froſts come on, and in winter they muſt be placed in a ſtove, kept moderately warm, where they will thrive and produce flowers the following ſummer.

SCUTELLARIA. (*From the form of the calyx, like a* ſcutellum, *a little diſh or faucer.*)

Lin. gen. n. 734. *Reich. n.* 792. *Schreb. n.* 989. *Juſſ.* 117. Caſſida. *Tournef. t.* 84.

Claſſ. 14. 1. Didynamia Gymnoſpermia.

Nat. order of *Verticillatæ. Labiatæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, very ſhort, tubular: *mouth* almoſt entire; after flowering cloſed with a lid.

COR. one-petalled, ringent: *tube* very ſhort, bent backwards: *throat* long, compreſſed: *upper lip* concave, trifid; *middle little ſegment* concave, emarginate; *ſide ones* flat, ſharpiſh, lying under the middle one: *lower lip* wider, emarginate.

STAM. *Filaments* four, concealed beneath the upper lip, of which two are longer. *Anthers* ſmall.

PIST. *Germ* four-parted. *Style* filiform, ſituation and length of the ſtamens. *Stigma* ſimple, curved in, acuminate.

PER. none. *Calyx* cloſed by a lid, helmet-ſhaped, doing the office of a capſule, three-ſided, opening by the lower margin.

SEEDS four, roundiſh.

OBS. *It is clearly diſtinguiſhed from all others by the fruit alone; for the calyx reſembles a helmet both in the lid and creſt. Hence Columna's and Tournefort's name of* Caſſida.

ESSENTIAL CHARACTER.

Calyx with an entire mouth, after flowering cloſed by a lid.

DESCRIPTIONS, *&c.*

[Theſe are all perennial plants, moſtly herbaceous, with ſquare ſtalks and oppoſite leaves: the flowers either ſolitary, axillary and naked, or elſe in terminating bracted ſpikes, with one bracte or floral leaf to each flower. Chiefly natives of the South of Europe and the Levant; two only indigenous of Britain. They flower in july and auguſt; ſome from june to october.]

1. Stems ſhrubby, ſpreading on the ground, and dividing into ſmall branches. Leaves cut, almoſt triangular, light green on the upper ſide, and downy on the under, ſtanding upon ſlender foot-ſtalks. Spikes ſhort. Corollas of a bright yellow colour. Seeds gray. It begins to flower at the end of may, and there is commonly a ſucceſſion of flowers for two months, and upwards.

[Stems about eight inches high, branched from the bottom, a line thick, hard, putting out fibres at the joint in that part which lies on the ground. Leaves eight or nine lines in length, and four or five in width, browniſh green but white beneath, cut like thoſe of Germander, on a petiole three or four lines long. Spike an inch and half in length, with pale-green bractes, ſeven or eight lines long; a yellow flower ſpringing from the axil of each. The whole plant is bitter [e].

In the Syſtema Vegetabilium it is ſaid that the corollas are purple with a white lip.

Tournefort has a variety, which is hoary, with the leaves more cut.

Native of the Levant and Barbary. Tournefort firſt introduced it into the Paris garden, and thoſe of Holland. Whence Mr. Miller had it in 1729 [f].

2. Very nearly allied to the preceding, but the corollas are white and larger [g]. In the Mantiſſa it is ſaid, that it very much reſembles the *peregrina*; but the leaves are more hairy, wrinkled and blunt, by no means ſhining; the bractes more ovate, pubeſcent, and ſofter; the corollas white, more cluſtered, and larger.

According to Loureiro, the ſtem is perennial, a foot high, tomentoſe, reddiſh, almoſt upright, but ſometimes creeping. Leaves blunt, petioled. Flowers pale, in ſhort leafy ſpikes.

Native of the Levant and Cochinchina. Introduced in 1780, by Monſ. Thouin [h].

3. This is very like the next ſpecies, but the corolla is violet-coloured with a whitiſh lip, and not yellow; the bractes are ovate, acute but not acuminate, ſhorter than the corolla, not equal to it. Leaves leſs oblong [i].

Stem procumbent and then erect, very much branched, from ſix inches to a foot in height. Leaves on ſhort petioles. Corolla pale violet, with the upper lip wholly white and ſomewhat hirſute [k]. According to Villars, it is of a fine blue, or whitiſh.

According to Loureiro, the ſtem is perennial, erect, a foot and half high. Leaves obtuſe, deeply crenate, tomentoſe. Corolla violet. Calyx entire, rounded, hairy.

[e] Tourneſ. voy. [f] Hort. kew. [g] Linn. ſyſt. [h] Hort. kew. [i] Linn. ſpec. [k] Krocker.

Digitized by Google

Native of Switzerland, Sileſia, Dauphiné, Piedmont, Cochinchina. Cultivated by Mr. Miller in 1752[l]: but omitted in the ſeventh and eighth editions of his Dictionary.]

4. Stems ſhrubby and trailing. Leaves cut on their edges, and ſmooth on both ſides. Corollas white or blue, larger than in any of the other ſpecies. [In Syſtema Vegetabilium it is ſaid that they are yellowiſh-white.

Native of Siberia. Cultivated by Mr. Miller in 1739[m].

5. Racemes lateral, with ſmaller, lanceolate, ſerrate leaves, and beſides theſe each pedicel has a briſtle on each ſide, as in *galericulata* and *peregrina*[n].

It has very much the air of the common ſort, but is higher and larger, with wider leaves more deeply toothed, and ſmaller flowers[o].

Native of Canada and Virginia. Cultivated in 1752, by Mr. Miller[p]: but diſcarded, with other ſpecies of little beauty, in the two laſt editions of his Dictionary.

6. Root ſlender, jointed, white and creeping. Stems from one to two feet high, upright, acutely quadrangular, with the ſides a little hollowed, and marked with two lines, jointed, ſtiffiſh, leafy, ſomewhat rugged, branched in the middle; the branches oppoſite and nearly upright. Leaves on very ſhort petioles, ſpreading, crenate almoſt equally from the baſe to the end, wrinkled, veined, pubeſcent with very ſhort hairs, paler beneath. The lower leaves are rather blunt, and the upper ones more pointed. According to Mr. Woodward, the ſtem and leaves are both nearly ſmooth; and the latter crenate at the baſe, but entire upwards. Mr. Curtis ſays that they are unequally crenate. Bractes two, very ſmall, briſtle-ſhaped, at the baſe of the peduncle. Flowers one on each ſide, ſubſeſſile, in pairs directed one way, nodding a little, blue and whitiſh underneath, hairy on the outſide. Calyx hairy, emarginate, fenced above with an arched ſcale, cloſing when the corolla falls off, and covered by the ſcale, which then increaſes in ſize, as with a lid. Seeds from one to four, of a pale brown colour, with a rugged ſurface[q].

The ſingular conſtruction of the calyx, ſays Mr. Curtis, is very deſerving of a minute attention. Accordingly it is remarked in Dr. Withering's arrangements, that when the bloſſom falls off the cup cloſes upon the ſeeds, which, when ripe, being ſtill ſmaller than the cup, could not poſſibly open its mouth, or overcome its elaſtic force, as the down of the ſeeds does in the compound flowers, and muſt conſequently remain without a poſſibility of eſcaping. But nature, ever full of reſources, finds a method to diſcharge them. The cup grows dry, and then divides into two diſtinct parts; and thus the ſeeds, already detached from the receptacle, fall to the ground.

Native of Europe, by the ſides of ditches, ponds and rivers. By our old authors called *Hooded Willow-herb* or *Looſe-ſtrife*.

It is ſingular that Ray, who ſeems to have enquired much after the medical qualities of plants, ſhould ſay, "de hujus viribus nihil invenimus a Botanicis traditum." When John Bauhin, whom he copies ſo frequently, calls it *Tertianaria*, from its ſuppoſed efficacy in curing intermittents. Haller ſays it is bitter, ſmells like Garlick, and has the ſame qualities with Scordium, but in a leſs degree. Curtis ſays it has ſcarcely any ſmell of Garlick; and Krocker that it has not either the ſmell or taſte of Scordium. Allione on the contrary affirms, that the ſmell is weaker than that of Scordium, but that it is more bitter; and that it has abſtergent qualities uſeful in correcting the bile, not without ſome degree of antiſceptic power. He adds, that it is not adequate to the removal of a violent Tertian, but that it is of ſervice where the fits are leſs violent, but more obſtinate. In ſuch caſes the expreſſed juice is given from one ounce to two ounces, or an infuſion of a handful or two of the herb.—With us it has never been received into practice.

7. Root creeping. Stem quite ſimple, ſcarcely the length of the finger, with about ſeven joints. Spike almoſt as long as the ſtem, directed one way, looſe, ſpreading, blue. Flowers ſolitary from each axil of the leaves, which being oppoſite, the flowers are in pairs. Leaves haſtate or ſagittate and eared together, eſpecially the lower ones, which are on longer petioles; whereas the upper ones are ſubſeſſile and ſagittate, but by no means eared; the floral-leaves are ovate-lanceolate; all are quite entire. The lower lip of the corolla is flexuoſe and quite entire. Branches ſeldom break out near the ground[r].

Stem ſtriated, villoſe at the joints, ſeldom branched at the axils. Leaves blunter than in the preceding, petioled, little or not at all notched, eared at the baſe. Flowers commonly in pairs: calyx hirſute, coloured, corolla blue; tube very long, angular, hirſute, erect, recurved at a right angle, white at the extremity; upper lip deep blue, trifid, with the middle ſegment arched; lower lip entire, convex in the middle, depreſſed at the ſides, having a groove along the middle and two riſings, emarginate in front, all blue; throat wide, having two cavities[s].

Scopoli remarks, that it is like the preceding, but the leaves are obtuſe, and the flowers larger. Linneus, in his Species Plantarum, doubts whether it may not be a variety of that; it being certainly very nearly allied to it.

Native of Sweden, on the coaſt, Auſtria, Goritia, Sileſia.

8. This is only one fourth of the ſize of the common ſort. The ſtem is branched at the baſe; the leaves are wider, leſs wrinkled, commonly quite entire, but ſometimes toothed at the baſe, and now and then haſtate. Flowers red or purple-fleſh-coloured, with a white lip, and blood-red dots[t].

Height four or ſix inches, ſometimes eight; often little or not at all branched in a wild ſtate, but in a garden becoming much branched, ſomewhat rigid and hirſute, purpliſh at the baſe. Leaves ſometimes ovate-lanceolate, having only a notch or two near the baſe, on very ſhort petioles, in ſhady ſituations ſmooth, in expoſed ones hirſute, ſometimes reddiſh. Flowers ſmall, pale red, or reddiſh-purple, the lateral ſegments of the upper lip ſomewhat diſtant, not under the middle one, the lower lip mottled within with deeper-coloured lines and dots. (Mr. Curtis found a ſingle plant with blue flowers.) Calyx with two lips, but very ſlightly cloven: upper lip with a flat ridge running acroſs it, which, when the bloſſom falls, enlarges, and preſſing down the upper lip, cloſes the mouth of the calyx, giving it the appearance of a helmet; middle ſegment rather ſhorter, nearly flat; lower lip broad, rather reflected, but neither notched at the end nor keeled beneath. Anthers white, ſlightly hirſute. Stigma a little hooked and pointed, ſlightly cloven[u].

Native of England, France, Alſace and Piedmont; on wet heaths and commons, in boggy ground, and at the edges of ponds, in a gravelly ſoil.

Gerarde firſt diſcovered this plant, "upon the bog (as he tells us) at the further end of Hampſtead-heath, and upon the ſame heath towards London, neer unto the head of the ſprings that were digged for water to be conveyed to London 1590, attempted by that careful citizen Sir John Hart, Knight, Lord Maior of the city of London: at which time myſelf was in his Lordſhip's company, and viewing for my pleaſure the ſame goodly ſprings, I found the ſaid plant, not heretofore remembred." It is ſaid ſtill to exiſt on Hampſtead-heath, but has been found more plentifully on Putney, Shirley, Streatham and other commons in Surry[x]; on Leweſdon-hill, by Mr. Baker; in Goldmire near Dalton, by Mr. Atkinſon; on Seaman's Moſs, next to Altringham, Cheſhire, by Mr. Caley[y]. On Wareham-heath and in Purbeck, Dorſetſhire, by Dr. Pulteney.

Linneus inſiſts that this is too nearly allied to the two preceding ſpecies; which, ſays Mr. Curtis, he would

[l] Hort. kew. [m] Idem. [n] Linn. ſpec. [o] Moriſon. [p] Hort. kew. [q] Smith and Curtis. [r] Linn. ſuec. [s] Krocker. [t] Smith. [u] Curtis, Withering. [x] Curtis. [y] Withering.

Digitized by Google

would not have done, if he had poſſeſſed the opportunity of ſeeing it frequently and cultivating it.

Allione, who as well as Ray has deſcribed the plant accurately, remarks that the ſeeds, which are kidney-ſhaped and black, when they are ripe remove the lip and ſpring out with an elaſtic force. This is a different proceſs from that which was related from Withering, in treating of the common ſort.]

9. Stems two feet high, ſending out many ſide branches. Lower leaves heart-ſhaped and ſerrate, ſtanding upon pretty long foot-ſtalks; upper leaves ovate and entire. Flowers in very long looſe ſpikes at the end of the branches; they are of a purple colour, and appear at the end of june: the ſeeds ripen in ſeptember.

Native of North America. [Cultivated by Mr. Miller in 1759.

10. This is a little tender herbaceous branching plant, procumbent with the branches riſing. Leaves blunt, ſmoothiſh, petioled, ſcarcely half an inch in length. Peduncles one-flowered. Flowers inodorous, blue: ſegments of the calyx roundiſh, quite entire and almoſt equal: lower lip of the corolla ſemitrifid and a little longer than the upper lip, the ſegments roundiſh, the middle emarginate and wider, the ſide ones quite entire.

Native of the Havannah, on maritime rocks; flowering in December [z].

11. Stem erect. Leaves ſeſſile, quite entire, rugged. Upper lip of the corolla with a hairy keel.—Native of Virginia [a].

12. Stems herbaceous, proſtrate, a ſpan high, ſimple, obſcurely four-cornered, ſmooth. Leaves an inch long, ſmooth on both ſides, paler beneath, almoſt veinleſs, remotely and bluntly toothed. Raceme flexuoſe, an inch and half long. Common peduncle pubeſcent. Flowers diſtant, alternate. A ſmall bracte on the pedicel, but none on the common peduncle. Calyx obliquely truncate, quite entire. Corolla pubeſcent, twice as long as the calyx [b].—Native of the Weſt Indies, Guadaloupe, &c.]

13. Stem hairy, two feet high. Flowers purple or white.

[According to Allione, the *Sc. peregrina* of Linneus is not the *Caſſida* of Columna, but the *Caſſida caule quadrangulo rubente, Teucrii ſerrato folio, flore cæruleo, labro albo*, of Tilli, in *hort. piſan.* He thus diſtinguiſhes them. Tilli's plant has the leaves ſmooth, veined beneath, dark green, firm, ovate, crenate-toothed, firſt with four teeth on each ſide, then three, and afterwards two. The floral leaves or bractes are entire and elliptic. The flowers are purple-violet with a white lip, five lines in length, not exceeding the internodes. The ſtems are browniſh-red, ſhining, ſmooth, bearing very long flowering-branches, which are ſcarcely erect. The flowering branchlets are ſomewhat hairy. The calyx is a little hirſute. The upper lip of the corolla ſomewhat hairy. But in the reſt of the flower there are ſcarcely any viſible hairs. Columna's Caſſida is only half the height of the other, and brachiate with the branches erect. The whole plant is hirſute, but extremely ſo next the flowers, and viſcid. The ſtems are green; the leaves alſo are green, ſoft, cordate, bluntly toothed, on longer petioles, and much bigger. Flowers large, blue, with the lower lip blue-purple not white, but ſpotted with white. The flowers alſo are longer than the internodes, and are about nine lines in length. The bractes are acuminate, awned, ſmaller than in Tilli's plant, but very hirſute.

Linneus ſays, there is another very like this, with the calyxes woolly, with gray hairs; the upper lip of the corolla hairy at the tip; the bractes ſhort and ovate [c]. And that there is a variety with white flowers, which is thicker, and has the leaves ſomewhat hairy [d].

Allione ſays, that the *Caſſida flore ex albo pallente* of Columna, which Linneus refers to his *albida*, is only a variety of his *Scutellaria Columnæ*.

[z] Jacqu. amer. pict. [a] Linn. mant. [b] Vahl. [c] Spec. [d] Syſt.

Native of Italy and Siberia. Cultivated in 1683, by Mr. James Sutherland [e].

14. The plant lies on the ground and has the appearance of Ground Ivy (*Glecoma hederacea.*) Stem ſomewhat rough, compoundly branched at top. Leaves ſuborbiculate, ſubovate (except the ſmall leaves coming from the corners of the greater ones, which are kidney-ſhaped:) obſcurely ſerrate, petioled, hairy. Flowers on ſhort pedicels, commonly by pairs, in terminating racemes. Bractes linear, very ſhort. Calyxes very ſhort without the tube of the mouth. Corollas narrow, longiſh [f].

Stem weak but upright, villoſe, a ſpan high. Branches few, oppoſite, like the ſtem. Leaves ovate, cordate, bluntly ſerrate, very finely villoſe, ſpreading, an inch long. Petiole the length of the leaf. Racemes directed one way, a finger's length. Corollas white [g].

Native of China, where it is called *Tim-gam-ſa*, and Japan.]

15. Stems three or four feet high, ſending out a few ſlender branches. Flowers purple, with longer tubes than any of the other ſorts.

Native of the Levant. [Cultivated in 1731, by Mr. Miller [h].

16. Stature of Nepeta; wholly hirſute. Calyxes of Scutellaria. Corollas almoſt of Teucrium, minute, rough-haired on the outſide: the upper lip ſeems to be very ſmall and emarginate. It may be doubted therefore whether it be a true ſpecies of Scutellaria or of Teucrium [i].]

Stalk woody, about two feet high, ſending out ſlender ſide-branches. Leaves hoary on their under ſides, and of a light green above. Flowers in pretty long terminating ſpikes, white, with ſmall bractes.

Native of Crete or Candia. Cultivated by Mr. Miller in 1759.

PROPAGATION AND CULTURE.

Theſe plants are all propagated by ſeeds. If theſe are ſown in autumn ſoon after they are ripe, they will more certainly ſucceed than when they are ſown in the ſpring, for ſometimes theſe miſcarry, and, if they ſucceed, the plants ſeldom come up the ſame ſeaſon. The ſeeds may either be ſown where the plants are to remain, or in a border to be afterwards removed; but as the firſt ſort does not bear tranſplanting well, unleſs removed young, the ſeeds of that had better be ſown where the plants are to ſtand. This ſhould be on a dry warm border of poor earth, where the plants will live much longer, and make a better appearance than on a rich ſoil, though they ſeldom continue more than two or three years. When the plants come up, they will require no other care but to thin them, and keep them clean from weeds.

When the other ſorts come up, and are fit to remove, they may be tranſplanted into a nurſery-bed at five or ſix inches diſtance, where they may ſtand till autumn, keeping them clean from weeds; then they may be tranſplanted into the borders of the flower-garden, where they are to remain.

DESCRIPTIONS, *&c.*

1. Root annual. Stem higher and weaker than Wheat, ſometimes attaining the height of ſix feet. Leaves a quarter or a third of an inch in breadth, rough to the touch, if the finger be drawn from point to baſe, but not hairy; they are wider, and form a more conſiderable tuft than Wheat commonly does. Spike very cloſe, of a gray colour from its pubeſcence, in a good ſoil and ſituation having four rows, containing from ſixty to eighty or even 120 grains, which are ſmaller and more ſlender than in Wheat. Haller mentions a variety with fourteen ſpikes, ſome of which were branched.

Gærtner deſcribes the ſeed as oblong, at top pubeſcent and as it were truncated, narrowed below and much acuminated, convex three-ſided on one ſide, and having a deep groove on the other: coat very thin membranaceous: albumen or body of the ſeed farinaceous, hardiſh, white: ſcutellum ovate-oblong, equal to about a third part of the ſeed, milky: embryo oblong, yellowiſh; plume oblong, compreſſed; radicles three, ſubcylindrical.

Some ſay that Rie is a native of Crete, and others of Siberia; but there is no reaſon to think that there is any country in which it is found wild. It flowers in june, and the grain is ripe in England about the middle of july.

Rie is eſteemed leſs nouriſhing than the other common grains, more ſuſceptible of fermentation, and in a ſmall degree laxative. It is uſed principally for making bread in northern countries, either alone or mixed with Wheat; and for extracting an ardent ſpirit.

2. This is an annual graſs, native of the South of Europe and the Levant.

3. Native of the Archipelago.

4. Native of Candia or Crete.]

PROPAGATION AND CULTURE.

The farmers diſtinguiſh the two varieties by the titles of Winter and Spring Rie, but when theſe are ſown three or four years, at the ſame ſeaſon, and on the ſame ſoil, it will be difficult to know them aſunder; but, where Rie is ſown upon a warm land, it will ripen much earlier than on cold ſtiff ground, and by continuing it two or three years, it will be forwarded ſo much, as to ripen a month earlier than the ſeeds which have long grown upon a ſtrong cold ſoil; ſo thoſe who are obliged to ſow Rie toward ſpring, generally provide themſelves with this early ſeed.

The Winter Rie is what the generality of farmers propagate; it is uſually ſown in autumn at the ſame ſeaſon with Wheat, and in many of the northern counties, as alſo in Wales, they are often mixed together, though I think it muſt be very bad huſbandry, for the Rie will always ripen ſooner than Wheat; ſo that if the latter is permitted to be fully ripe, the former will ſhatter.

It is generally ſown two buſhels and a half to the acre, upon poor, dry, gravelly, or ſandy land, where Wheat will not thrive, and in ſuch places may anſwer very well; but on ſuch land as will bear Wheat it is not proper to ſow Rie, as the value of it is greatly inferior to that of Wheat.

When Rie is ſown, the ground ſhould not be too wet; and if it ſhould happen that much rain falls before the Rie is come up, it often rots in the ground; but it is not long in coming up, it being much ſooner out of the ground than Wheat.

The ſmall Rie may be ſown in the ſpring about the ſame time with Oats, and is uſually ripe as ſoon as the other ſort; but if the ſeaſon proves wet, it is apt to run much to ſtraw, and then the grain is generally lighter than the other; ſo the only uſe of this ſort, is to ſow upon ſuch lands where the autumnal crop may have miſcarried.

The general uſe of Rie is for bread, either alone, or mixed with Wheat.

Rie is alſo ſown in autumn to afford green feed for ewes and lambs in the ſpring, before there is plenty of Graſs. When this is intended, the Rie ſhould be ſown early in autumn that it may have ſtrength to furniſh early feed. The great uſe of this is to ſupply the want of Turneps in thoſe places where they have failed, as alſo, after the Turneps are over, and before the Graſs is grown enough, to ſupply green feed for the ewes; ſo that in thoſe ſeaſons, when the Turneps in general fail, it is very good huſbandry to ſow the land

Digitized by Google

land with Rie, eſpecially where there are ſtocks of ſheep, which cannot be well ſupported, where green feed is wanting early in the ſpring; therefore thoſe farmers who have live large ſtocks, ſhould have ſeveral methods of ſupplying themſelves with ſufficient feed, leſt ſome ſhould fail; for as Turneps are a very precarious crop, ſome land ſhould be ſown with Cole-ſeed, which will ſupply the want of Turneps in winter; and if ſome of the ground, which was ſown late with Turneps which had failed, was ſown in autumn with Rie, that would be fit to ſupply the want of Cole-ſeed afterward.

[Rie is alſo uſed for ſoiling great cattle and horſes. A good acre will keep ſix horſes a fortnight[k].

As a grain for making bread, &c. Rie is ſown to a much greater extent in Germany, Switzerland, and the northern and alpine countries, than in England. In cold and moiſt vallies among the mountains it is their moſt uſeful crop, and in many places the chief reſource of the hardy inhabitants.

In Le Devoluy, a diſtrict of Dauphiné, elevated from twelve to eighteen hundred yards above the level of the ſea, they grow abundance of this grain, which they keep two or three years in the ſtraw, in round ſtacks ſet up in the field, containing from four or ſix hundred to a thouſand ſheaves; the ears being all turned into the middle, the grain thus keeps extremely well, provided it is dry before it is put off, and that there be no graſs or weeds among the ſtraw: the grain is fine, well fed, and fit for ſeed after three or four years; it has not that pale colour which is uſual in Rie, but acquires a yellow hue approaching to that of Wheat. Hardened by the climate, like the men and animals of the ſame country, it carries better, and furniſhes ſeed for thoſe milder ſituations, where the crop is apt to be choked by weeds, and weakened by the ſtifled air of the cloſe vallies.

Spring Rie produces a leſs crop of ſmaller, lighter grain than Winter Rie; it is eſteemed leſs nouriſhing, and bread made of it is of a darker colour[l].

Rie-flour is uſed in the Limoſin, a province of France, with great ſucceſs, for fattening of oxen; after they have had a ſummer's graſs, and have been put to Turneps the beginning of november, or end of october. When theſe fail, they mix the flour with water to the conſiſtency of a paſte, and leave it three, four or five days to ferment and become ſour; when they dilute it with water, and thicken this water with hay cut. Some add leaven to the paſte, to ſecure a fermentation, but none give it, till it is ſour: it is given thrice a day, and a large ox will eat a boiſſeau, weighing twenty-two pounds. The moſt approved method is to give the ſour regimen for the laſt three weeks[m].

DESCRIPTION, &c.

This plant has the habit of the Cucurbitaceæ or Cucumber and Melon tribe, and climbs like them by tendrils. Leaves cordate-angular, rugged on the upper ſurface, with the angles toothed and acute, alternate, on a ſmooth petiole. Flowers ſmall, without ſcent. Corollas yellow. The males on many-flowered axillary peduncles; the females one or two only on a peduncle from the ſame axil. Fruit green and ſhining on the outſide; whitiſh and fleſhy within; differing in ſize and ſingular in ſtructure. The ſeed is green and naked, and in larger fruits an inch long; it is placed at the very apex of the fruit. When it is ripe, it protrudes itſelf a little, and puts forth many fibres at its extremity, which it lets drop into the earth. In the oppoſite part, between the lamellæ, it puts forth a leafy ſtem, and then the fruit gradually putrefies. Although the moiſture of the fruit itſelf be ſufficient to make the ſeed vegetate, and to afford it nutriment, until the fibres reach the ſoil and imbibe nutriment from thence; yet the people of the country bury it in the ground, probably to accelerate the growth, or to inſure it with more certainty: it will however grow, if it fall on the ground, or even if it be preſerved any where. In the iſland of Cuba they eat it in their ſoup, or pudding, or boiled with their meat conſtantly[n]. Browne ſays, that the fruit is ſometimes boiled in Jamaica, and ſerved up at table by way of green, in which ſtate it is generally looked upon as wholeſome and refreſhing; but it is too inſipid to be much liked. The apples ſerve to fatten the hogs in the mountains and inland parts, where the plant is moſtly cultivated.

Native of the Weſt Indies. Flowering and fruiting there in december.

The natives of Cuba notice two varieties: one, which is moſt common, they call ſimply *Chayote*; it is beſet with harmleſs prickles, ſometimes in great abundance, and ſometimes with very few; it is about four inches in length: the other, leſs frequent, called *Chayote francés*, is for the moſt entirely deſtitute of prickles, and is the ſize of a hen's egg[o].

SECURIDĀCA. (*So named from the pod being in the ſhape of a* ſecuris, *ax or bill-hook.*)

Lin. gen. n. 852. *Reich. n.* 922. *Schreb. n.* 1156. *Jacqu. amer.* 197. *Juſſ.* 366.

Claſſ. 17. 3. Diadelphia Octandria.

Nat. order of *Papilionaceæ* or *Leguminoſæ*.

GENERIC CHARACTER.

CAL. *Perianth* three-leaved, ſmall, deciduous; *leaflets* ovate, coloured; the uppermoſt reſpecting the ſtandard, and two the keel.

COR. papilionaceous, five-petalled.

Wings ſpreading wide and very blunt.

Standard two-leaved, oblong, ſtraight, connate with the keel at the baſe, reflexed at the tip.

Keel length of the wings, ſubcylindrical, with the limb or border wider, augmented by a plaited blunt appendicle.

STAM. *Filaments* eight, connate at bottom. *Anthers* oblong, erect.

DESCRIPTIONS, *&c.*

1. This is an upright tree twelve feet in height, with few long ſlender weak branches. Flowers in racemes, purple: ſtandard obtuſe, wings roundiſh, appendix of the keel compreſſed and reflexed.
Native of Martinico, flowering there in april [p].
2. This is a ſhrubby, ſcandent plant: the younger leafy branchlets are changed into very ſtrong tendrils. Leaves oblong-ovate, obtuſe, quite entire, ſmooth, alternate, petioled. Racemes looſe, lateral, oppoſite to the leaves. Flowers without ſcent, red; with the ſtandard acute, the wings oblong and attenuated at the baſe, and a wide appendix to the keel [q].—Native of South America and the Weſt Indies. Found in Jamaica by Browne, and at Carthagena by Jacquin. Introduced in 1786, by Mr. Alexander Anderſon [r].
3. Native of Jamaica and Hiſpaniola. Browne's firſt ſpecies belongs to this, and not to the *erecta*, where Linnæus had placed it. In that the leaves are oblong, and the branches thicker, more ſtraight, ſtiff and upright [s].

30. Sedum nudum. *Naked-branched Stonecrop.*

Willd. ſpec. 769. *Ait. kew.* 2. 112.

Leaves ſcattered oblong-cylindrical blunt, ſtems ſhrubby very much branched, branches twiſted, cymes terminating.

DESCRIPTIONS, *&c.*

1. Stem a foot high, erect, round. Leaves lanceolate, ſcarcely a finger's length, equally ſerrate, even, ſharpiſh, not very fleſhy. Racemes axillary, ſmall, ſolitary. Flowers ſmall, with a five-toothed calyx, five petals, ten ſtamens, and five piſtils.

Native of the moſt ſouthern parts of Europe and of Siberia[t].

2. Root perennial, tuberous. Stems from one to two feet high and upwards, upright, ſimple or unbranched, leafy, round, ſmooth, ſolid, reddiſh and often dotted with red. Leaves almoſt covering the ſtem, ſeſſile, ovate, fleſhy, tooth-ſerrate, ſmooth and even, of a blueiſh green colour. Corymbs terminating, many-flowered, cloſe or heaped together. Flowers deep purple, very rarely white in England[u]; though that ſeems to be the moſt common colour in ſome foreign countries.—Capſules leguminous, oblong, filiform-beaked, membranaceous. Seeds irregular, ſomewhat like ſawduſt, very finely ſtriated longitudinally, pale, faſtened in ſeveral rows to the margin of the gaping future[x].

This is the only Engliſh Sedum with flat leaves. Being a handſome plant and eaſily cultivated, it is met with in moſt gardens, where it will ſometimes grow a yard high. The leaves are ſometimes found entire at the edge; the flowers vary in colour[y]; and the plant in ſize. Hence ſeveral varieties noticed by old authors, by Linneus, and by Aiton in the Hortus Kewenſis. Haller conſiders the laſt variety as a diſtinct ſpecies. It has branches from all the axils, and is naked between the branches. The leaves are conjugate, patulous, ovate, toothed here and there. Flowers white, very ſlightly tinged with red, with a greeniſh

[t] Linn. amoen. [u] Smith and Curtis. [x] Gærtner. [y] Curtis.

line

Digitized by Google

line along the middle, in close umbels on the stem and branches. Anthers scarlet. Whereas in the common Orpine, the stem is quite simple, wholly covered with leaves, which are sharper, more sharply serrate, ascending, and disposed irregularly. Anthers ferruginous.

The *hæmatodes* of Miller seems to be the same with this large variety.] The stalks are thick, succulent, round, near three feet high; leaves ovate, entire, three inches long by two and a quarter wide, placed by pairs, of a pale herbaceous colour, the upper ones embracing. Flowers in large terminating bunches, white or purple.

Native of Portugal; [as is also variety γ. Spain and Switzerland. The common white and purple Orpine (α and β) are common in most parts of Europe, Japan and Siberia: on old walls, by the side of woods, in hedges, among bushes in pastures, in fields, in vineyards, chiefly in a chalky or sandy soil; flowering in july and august. The purple-flowering Orpine is most common in Britain. This name is from the French. It was also called *Live-long*, because a branch of it hung up will keep its verdure a long time.

Near London it occurs about Charlton, Shooter's-hill, Norwood, &c. Shelford and Burrough-green in Cambridgeshire: Aspley-wood in Bedfordshire: Headington-Wick copse, and Shotover-hill, Oxfordshire: in Suffolk frequent: near Ashburne in Derbyshire: Malvern Chace: about Manchester: near Shrewsbury: Tettenhall in Staffordshire. Castle Dikes, Preston woods, &c. in Northamptonshire. Between Glasgow and Dumbarton, and two miles eastward of the latter, Scotland.

A decoction of the leaves in milk is a forcible diuretic. It has been given with success to cure the piles. Kine, goats, sheep and swine eat it, but horses refuse it, according to the observations of Linneus [e].]

3. Roots fibrous, perennial. Stems trailing. Leaves standing alternate round the stems, almost an inch long, and half an inch broad. Flowers in a compact corymb, sitting close on the top of the stem: they are star-shaped, of a purple colour, and appear in july. It is an evergreen. [Linneus says that the leaves fall in winter; so also says Caspar Bauhin: Loureiro agrees with Miller. But he attributes yellow flowers to his plant.—Mr. Curtis remarks, that the singular manner in which the leaves are attached to the flowering stem deserves to be noticed.

Native of Germany; Switzerland about Aigle and in the Valais; the South of France; Italy; China, Cochinchina and Japan, growing out of the crevices of rocks. Cultivated in 1596, by Gerarde [a].

4. Native of Madeira; where it was found by Masson, and introduced in 1777. It is shrubby, and flowers in june and july [b].]

5. Root perennial, composed of many thick fleshy fibres, from which come out several stalks rising near a foot high. Leaves alternate on every side, thick, two inches and a half long, and three quarters of an inch broad, and slightly serrate. Flowers bright yellow; petals lanceolate, erect, spreading out at the top; stamens large, erect, with oval, sulphur-coloured anthers. [Capsules ovate-oblong, compressed, united at the base, from upright spreading, purplish, with the gaping future white and reflexed. Seeds oblong, subcylindrical, thicker outwards, obtuse, rugged-striated, ferruginous. Embryo the size of the seed [c].

Native of Siberia. Cultivated by Mr. Miller in 1759. It flowers from july to september [d].

6. This rises with very numerous slender stems of about two feet in height, and often of a red cast on the upper part: the leaves are cuneiform, sessile, fleshy, smooth, and either crenated or obtusely serrated; the serratures being generally three or four on each side: the leaves on the upper part of the stems are longer and narrower than on other parts: the terminal cyme is commonly three-parted, and sometimes, though rarely, many-parted: the peduncles flexuous, often dichotomous, and sometimes farther subdivided: the bractes are double, one large and cuneiform, the other setaceous and very short: the flowers are sulphur-coloured, with carinated, sharp-pointed petals [e].

Native of Tartary, at the foot of the Uralian mountains, about Trebisond. Cultivated in 1766, by Peter Collinson, Esq. [f]

7. This is extremely like *Saxifraga rotundifolia*, but the leaves are cordate, thick and fleshy, and the fructification is that of *Sedum*.—Stem herbaceous, branched, erect, patulous, even, a foot high. Leaves alternate, remote, only at the ramifications, blunt, fleshy, smooth. Panicles short, not longer than the leaves. Calyx small. Petals lanceolate, sessile, white, unspotted, spreading. Anthers red.

Native of Siberia [g]; where it was discovered by Professor Pallas, the celebrated Russian naturalist; and introduced by him, in the year 1780, into the royal garden at Kew [h].

When the plant grows in an open situation, exposed to the sun, the leaves and stalks become of a bright red colour. It is the only hardy Sedum cultivated with us that has a shrubby stalk: the leaves are deciduous. It flowers in july and august, and is proper for a rock plant, with most of the other Sedums [i].]

8. This is a low annual plant. The stalks rise three inches high, dividing at top into two or three parts. The flowers come out singly from the side of the stalk; they are white, star-pointed, and are succeeded by star-pointed rough capsules.

[Stem erect, angular. Lowest leaves commonly opposite, the rest scattered, wedge-shaped, angular seven-toothed, ciliate with pellucid scalelets, each surface very finely striated, and having very small shining dots. Cyme bifid, leafy. Flowers sessile in the axils of the floral leaves; which are obovate; the lower five or three-toothed, the upper entire. Calyx-leaves lanceolate, acute, erect. Petals narrower but scarcely shorter, lanceolate, acute, compressed, white with a red keel. Stamens and germs shorter than the petals, white. Stigmas purple. Capsules diverging. The five scales, which are the nectaries, in this species are lemon-coloured, somewhat oblong, under the germs. In the *populifolium* they are roundish, and white tending a very little towards yellowness. In the *Telephium*, they are truncate, linear, longer. In the *hispanicum* truncate, emarginate, reddish-yellow. In the *rupestre* truncate and yellow [k].

Native of Germany, France, Switzerland, Italy; and, according to Loureiro, of China, about Canton. Cultivated in the botanic garden belonging to the Company of Apothecaries at Chelsea, in 1739 [l].

9. Root biennial. Stem erect, branched. Flowers white, on long peduncles.—Native of Piedmont, in shady stony places [m].]

10. Root annual. Stalks six or seven inches high, dividing into smaller branches, which sustain small white flowers growing in large panicles.

[Lower leaves like those of wild Thyme, only succulent; upper alternate, from a thick petiole reflexed, wide, ovate. Flowers on tender peduncles. Calyx hirsute, not more than a third of the petals in length. Petals lanceolate, awned, white divided by a purple line [n].

Native of Germany, France, Switzerland and Italy. Cultivated here in 1640, as appears from Parkinson [o].

β. Stem erect. Lower leaves in threes and fours, the next opposite, the uppermost alternate. Racemes axillary, but nearer. Petals purple.—Native of Piedmont [p].

11. This has the appearance of *Sempervivum montanum*. Root-leaves acute, smooth, quite entire. Stem by the side of the root, ascending, half a foot high, having a few scattered linear sharp leaves at bottom. Raceme terminating, length of the stem; pedicels scattered, commonly two-flowered. Capsules not diverging, surrounded by the calyx. It is a perennial plant, found in Palestine, by Hasselquist [q].

12. Root perennial, compoſed of ſmall white fibres. Stems numerous, weak, proſtrate and creeping, about three inches long or ſomewhat more, branched, in tufts, round, weak, clammy, leafy. Flowering branches erect. Leaves moſtly oppoſite, cloſely imbricate, ſeſſile, very thick and fleſhy, broader than long, convex on the lower, nearly plane on the upper ſurface, glaucous often with a tinge of purple; dotted and ſometimes having a net of red veins: on the flowering-branches they are alternate. Panicle terminating, ſpreading, few-flowered. Calyx downy, clammy. Petals white, with a purple keel, three times the length of the calyx. Nectaries, ſmall yellow glands, placed externally at the baſe of each germ. Anthers dark red. Capſules pale brown. Seeds yellowiſh. This ſpecies has generally one ſixth part more through the whole of the fructification than the other Sedums: as ſix ſegments to the calyx; ſix petals to the corolla; ſix nectaries; twelve ſtamens; and ſix piſtils [r].

Linneus marks it as annual; Dr. Smith has ſometimes thought it biennial, but he reſts in ſuppoſing it to be perennial; frequently however diſappearing in one ſpot, and re-appearing in another.

Native of many parts of Europe, as France, England, Switzerland, Auſtria, Spain, Portugal, Italy; alſo of Barbary; in the fiſſures of rocks and on walls: flowering in june. In England it is not uncommon on walls near London; as near Chelſea Hoſpital; between Kenſington gravel-pits and Acton; Hammerſmith, Kew, &c.; at Fulbourn, in Cambridgeſhire; Market-ſtreet, in Bedfordſhire, and Market-Eit near that, where it ſeems to have been firſt found by Mr. Thomas Knowlton; at Bugden in Huntingdonſhire, obſerved by Mr. Woodward; at Malton in Yorkſhire, by Archdeacon Pierſon; at Cliſton near Briſtol, by Mr. T. W. Dyer.

This pretty little Sedum, introduced into a garden, propagates itſelf freely upon walls, in waſte places, and about garden pots. No plant is better adapted to the purpoſe of decorating rock-work; where it grows without any trouble, in any aſpect, multiplying very much by young ſhoots, and looking beautiful throughout the year [s].

13. Root perennial. Stems round, leafy, branched at the baſe, often hanging down, erect at the top. Leaves ſcattered, alternate, adnate-ſeſſile, looſe at the baſe and produced, erect above, compreſſed, acuminate, extremely ſucculent, ſmooth, rather glaucous, frequently tinged with red; the lower ones turned back; when old they eaſily fall off. Flowers in a terminating ſubcymed panicle, with many-flowered branches, for the moſt part recurved. Flowers erect, bright yellow, with a fifth part added very frequently to the natural number in the fructification; as is common in this natural order. Calyx acute, divided almoſt to the baſe, ſmooth [t].

Leers remarks, that it very frequently varies with ſix, ſeven, eight or nine petals, with as many germs, and double the number of ſtamens. Haller alſo ſays he has ſeen from five to eight petals; and that it has commonly ſix petals and as many capſules, with twice the number of ſtamens. And Villars, that it has ſeven petals and fourteen ſtamens in the firſt and principal flower; but ſix petals and twelve ſtamens in the others.

Native of Europe. Common in England on walls and thatched roofs; and on rocks in the northern counties: flowering in july. Haller ſays it is eaten in ſalads.

14. This is a villoſe plant, with an upright ſtem, branched at top. Branches filiform, panicled. Panicle patulous. Leaves ſcattered, fleſhy, ſpreading, compreſſed above. Flowers numerous; each on a capillary pedicel. Calyx very ſmall, five or ſix-parted. Corolla gold-coloured, five or ſix-petalled: petals lanceolate, acute. Stamens ten or twelve, ſhorter than the corolla.—It is allied to the preceding, but differs in the ſtem, leaves and branchlets being pubeſcent; the panicle patulous; the flowers on longer pedicels, and not all directed one way. Annual.—Native of Barbary [u].

15. Native of Portugal. Perennial. Introduced in 1774, by Meſſrs. Kennedy and Lee. It flowers in june and july [x].

16. This is a little ſmaller than the *reflexum*. Leaves cloſely imbricate (before flowering) in five or ſix rows, glaucous, flatted a little, acuminate; on the flowering ſtem ſomewhat remote; as in *S. reflexum*, all erect, not bent back at the point. Dr. Withering remarks, that the diſpoſition of the leaves in five or ſix rows may be beſt obſerved by viewing the plant with the ends of the branches oppoſed to the eye. Panicle ſubcymed, many-flowered, with the branchlets ſcarcely reflexed. Flowers of a bright yellow or gold colour, often ſix-cleft. Calyx bluntiſh, glaucous, reddiſh, one-leafed at the baſe [y].—According to Withering, the flowers have frequently ſix or ſeven parts.

Reichard diſtinguiſhes this from *Sempervivum ſediforme*, by its having the leaves gradually narrowed into a ſharp point: the petals yellow, and a great deal of the upper part of the ſtem always nodding, till it is in full flower.

Native of England and Wales, Germany, Carniola, Sileſia, Dauphiné, Piedmont, on rocks and walls: flowering in july. Perennial.

It was firſt obſerved by Merret, on St. Vincent's rocks near Briſtol; next by Lhwyd and Richardſon in Wales; thirdly by Dillenius, in 1726, on Chedder rocks in Somerſetſhire; and fourthly by Robſon, on walls about Darlington.—Both this and *reflexum* are cultivated in Holland and Germany, to mix with lettuces in ſalads; the taſte is acrid [z].

17. Root annual. Stems woody, half a foot high, branched, brachiate, diffuſed, procumbent. Leaves ſeſſile, alternate, green never red, ſparkling in the ſun. Flowers ſeſſile on one ſide of the branches, on hard pedicels a line or two in length. Calyx-leaves blunt, green. Petals yellow, lanceolate [a].

Native of Norway, Germany, Switzerland, Dauphiné, Mont Cenis, &c. on rocks.

18. Flowers yellow, four-petalled.—Native of the moſt northern part of Aſia, on rocks. Perennial [b].

19. Root ſlender, fibrous, perennial. Stems ſeveral, a hand high, reclining at the baſe, and then erect, round, tinged with red. Leaves, on the flowering ſtems, pale green dotted with purple, oblong, thickiſh, round on one ſide and flat on the other; towards the top, under the flowers, more ſwelling and ſhorter: leaves on young plants or barren ſhoots, in bundles, glaucous without any purple dots, thinner, from a narrow baſe widening gradually, and ending in a blunt point. The ſtems divide at top into a few branchlets, forming a ſort of umbel, (or rather cyme,) bearing ſeſſile, ſtar-like white flowers, ſtained with pale purple from a purple groove running along the petals: theſe are ſix, ſometimes ſeven in number, keeled and cuſped. Capſules as many; and ſtamens twice as many as the petals; with round brown anthers. Calyx ſhort, having as many ſegments as there are petals in the corolla. The flowering branches lengthen out in time into a ſort of ſpike moderately reflexed: and then they, with the leaves under the flowers, calyxes, capſules, and even the corollas on the outſide, become covered with a fine pubeſcence. The leaves alſo on the ſtems and ſhoots are ſomewhat harſh to the touch [c].

Native of Spain and Carinthia. Cultivated in 1732, by James Sherard, M.D. at Eltham. It flowers in july [d].

20. Stem ſmooth, ſimple, ſeldom branched. Leaves embracing, acute, ſmooth, ſpreading, an inch long. Flowers yellow, in a compound cyme, which is trifid, with the middle flower ſeſſile.—Native of Japan: flowering there in june [e].

21. The whole plant ſmooth. Stem a finger's length, purpliſh, in a poor ſoil ſimple, but branched in a richer ſoil. Branches of the ſame height and ſtructure with the ſtem, alternate or ſcattered, ſimple.

[r] Smith, Curtis, Woodw. Mſs. [s] Engl. bot. and Curtis. [t] Smith. [u] Desfontaines. [x] Hort. kew. [y] Smith. [z] Withering. [a] Haller. [b] Pallas. [c] Dillenius. [d] Hort. kew. [e] Thunberg.

Leaves

Leaves green tinged with purple, or wholly red. Peduncles divaricating, flexuoſe, ſometimes bifid, having a ſingle leaf under each ramification of the ſame ſtructure with the others. Pedicels alternate, ſpreading very much. Flowers ſmall. Calyx ſhorter than the petals; which are lanceolate, of a violet-purple colour. Nectareous ſcales truncate, mucronate, at the baſe of the germ. Filaments the length of the petals; ſometimes, but rarely, there are twelve. Anthers globular, purple. Germs five, ovate, acuminate, white, length of the filaments.

Found by Vahl, in the clefts of rocks by Manub in Tunis [f].

The above is different from the *Sedum cæruleum* of Linneus's mantiſſa, (p. 241.) which he took up on the authority of Willich. But Thunberg did not find any ſpecies of Sedum at the Cape of Good Hope [g].

22. Root perennial, fibrous. Stems decumbent at bottom, and there throwing out fibres; flowering ſtems upright, from three inches to a ſpan in height, round, leafy, branched, ſmooth. Leaves ſcattered thinly, ſpreading out horizontally, ſeſſile, cylindrical, very blunt, ſmooth, fleſhy, ſomewhat glaucous and generally reddiſh. Panicle terminating, alternately branched, ſubcymoſe, many-flowered, ſmooth. Calyx blunt, even. Petals white or red: generally white with a red ſtreak, and a general tinge of red. The whole plant has ſometimes a purpliſh hue. Anthers deep red. The cylindric oblong ſhape of the leaves readily diſtinguiſhes this from other Engliſh Stonecrops [h].

Native of Europe, on rocks, walls and roofs, flowering in july. Near London, at Kentiſh-town, and between Bromley and Bromley-hall in Middleſex. At Peterborough, on walls. On rocks above Great Malvern. Wick Clifts. At Chattereſs in the Iſle of Ely. At Stevington and Sharnbrook in Bedfordſhire, by the Rev. Mr. Abbot.

Haller informs us, that it poſſeſſes all the virtues of the large Houſeleek, and that he has uſed the juice of it in uterine hæmorrhages. By way of cataplaſm it is applied to the piles when in a painful ſtate. It is eaten by ſome as a pickle [i].

23. Root perennial, fibrous. Stems numerous, growing in tufts, much branched, decumbent, and creeping at the baſe, then upright, three inches high, ſmooth, round, very leafy. Leaves cloſely imbricate, blunt, flatted a little, from upright ſpreading, looſe at the baſe. Cymes terminating, ſolitary, few-flowered. Flowers erect, ſeſſile. Calyx bluntiſh, even. Petals acute, yellow, twice the length of the calyx. Filaments the length of the corolla. Anthers and germs yellow. Seeds reddiſh brown. The whole plant is acrid [k]; and chewed in the mouth has a very hot biting taſte; whence, and from its common place of growth, it has the name of *Wall-Pepper*. Applied to the ſkin it bliſters; and taken inwardly it excites vomiting. In ſcorbutic caſes, and quartan agues, it is an excellent medicine under proper management [l].—For the former, a handful of the herb is directed to be boiled in eight pints of beer till they are reduced to four, of which three or four ounces are to be taken every morning. Milk has been found to anſwer this purpoſe better than beer. Not only ulcers ſimply ſcorbutic, but thoſe of a ſcrophulous or even cancerous tendency, have been cured by the uſe of this plant. It is likewiſe uſeful as an external application, in deſtroying fungous fleſh, and in promoting a diſcharge in gangrenes and carbuncles [m].

Native of Europe, in dry ſandy and gravelly paſtures, on houſes, walls, banks and rocks. Common in England; flowering in june. Planted in a pot, it will hang over the ſides, and cover the pot completely. It will continue to grow, when hung up in the open air or in a room; which has been conſidered as a proof that it receives its nouriſhment principally from the air; but it is juſtly remarked by Dr. Withering, that though the life of the plant be thus retained for ſome weeks, yet it is at the expenſe of the juices which its ſucculent leaves had previouſly imbibed. At the end of three weeks, a plant, ſuſpended by Mr. Gough of Kendal before a window with a northern aſpect, had loſt about half its weight, though it had put out ſome fine fibres from the root, and had yet life enough to enable it to turn to the light, after having been purpoſely turned from it. After being kept in water for twenty-four hours, it regained more than half of what it had loſt. Mr. Gough therefore juſtly conſiders the ſucculent leaves as reſervoirs, which ſupport the plant in dry weather, and are again repleniſhed in rainy ſeaſons; but does not admit that ſuch plants attract nouriſhment from the air more than others [n]. It muſt be allowed however that they ſubſiſt much upon the humidity of the atmoſphere, ſince their ſucculent ſtems and leaves cannot derive much nutriment from the arid ſoil in which they generally grow.

24. Inſipid Stonecrop has the habit of the preceding or biting Stonecrop, but is ſomewhat larger. The leaves are ſubcylindrical; not ovate, and come out moſtly by threes in a double row, and hence appear to be imbricate in ſix rows; this is moſt obvious in the young ſhoots: they are very ſpreading, looſe at the baſe, and ſcarcely gibbous. The cyme is leafy. The flowers of a golden yellow colour. The herb not acrid [o].

The leaves of the *acre* are ſhort, broad at the baſe, and remote; but in this they are nearly of the ſame thickneſs throughout, longer and more numerous; they are alſo in general much redder. The *acre* flowers a fortnight ſooner than the *ſexangulare* [p]. Dr. Withering obſerves, that the number of ſtamens, &c. is uncertain, varying from eight to twelve.

Native of ſeveral parts of Europe, on walls, roofs and dry paſtures; flowering at the end of june.—On Greenwich Park wall. Near Northfleet, Sheerneſs, and in the Iſle of Shepey. Near Trinity Conduit head, between Cambridge and Madingley, and on Ely Minſter.

25. Root annual, fibrous. Stems in tufts, decumbent at the baſe, ſmooth, red, leafy. Leaves moſtly alternate or nearly oppoſite, bluntiſh, ſomewhat glaucous, produced and looſe at the baſe. Cymes terminating, ſolitary, almoſt leafleſs, racemed. Flowers erect, five-cleft. Calyx blunt, even. Petals acuminate, white with a red keel, ſometimes dotted with a red point. Capſules membranaceous, even [q]. It has been confounded with the next ſpecies.

Native of Britain and Norway: on rocks, ſandy coaſts, roofs and walls. On the ſandy downs of the Norfolk and Suffolk coaſt plentifully; as well as in Devonſhire, Dorſetſhire, Cornwall, Wales and Scotland. On the mountains of Weſtmoreland and Lancaſhire.]

26. This is an annual plant, with an erect ſtalk, ſeldom riſing above two or three inches high. The leaves are of a grayiſh colour. The flowers are ſmall and white, and grow at the top of the ſtalk in a reflexed ſpike.

[It is thus deſcribed by Retzius.—Root annual, fibrous. Stem branched, ſmooth. Leaves ſcattered, ovate, gibbous, ſeſſile, ſpotted with purple. Cyme properly none, but the branches recurved and flowering. Flowers on the interior or upper ſide of the branches, on ſhort peduncles, alternate, having for the moſt part a leaf to each flower. Calyx-leaves ovate, gibbous, ſpotted. Petals ovate-lanceolate, concave, leſs than the calyx, yellow. Stamens a little ſhorter than the petals. Germs erect, compreſſed, lanceolate, with very ſhort ſtyles and ſtigmas. Capſules diverging, ſpotted with red, with a groove running along the upper part.

Native of the North of Europe. Cultivated in 1768, by Mr. Miller [r]: who miſtook it for the preceding ſpecies.

27. Root annual. Stem a hand or more in height, upright, fleſhy, very much branched, ſhrubby at

[f] Vahl. [g] Willdenow. [h] Smith, Curtis, Withering. [i] Curtis. [k] Smith and Curtis. [l] Withering. [m] Woodville. [n] Wither. arr. [o] Smith. [p] Curtis. [q] Smith. [r] Hort. kew.

bottom.

bottom. Branches frequent, ſcattered or alternate, but ſometimes oppoſite, upright, round, frequently tinged with purple. Leaves adnate a little above the baſe, alternate, flattiſh above, channelled towards the baſe, convex beneath, glaucous, often purpliſh; the uppermoſt ovate. Cyme terminating, bifid, many-flowered. Peduncles ſcarcely branched: pedicels alternate, ſolitary, one-flowered; and ſometimes a flowering branchlet or two below the cyme. Calyx-leaves ovate, obtuſe, not fleſhy. Petals channelled, villoſe on the outſide, yellow, dotted with purple within, the ſame ſize as in *S. acre*; according to Desfontaines ſix in number. The whole plant is pubeſcent.

Found by Vahl in clefts of rocks in the kingdom of Tunis [s].

28. Root perennial, ſmall, fibrous. Stem from three to five inches high, upright, leafy, round, ſpotted; the lower part and the lower leaves ſmooth, the upper part viſcid and hairy; branched at bottom. Leaves blunt, fleſhy, convex at the back, flat above, often red, ſometimes a little rough at the back with viſcid-pointed hairs, eſpecially the uppermoſt. Panicle cymed, terminating, pubeſcent, viſcid. Calyx alſo hairy-viſcid and blunt. Petals white or roſe-coloured, with a red rib. Anthers red. Capſules acuminate, rugged, brown or purpliſh [t].

Native of Britain, Germany, France, Italy, Switzerland, Denmark. In bogs and moiſt meadows in the northern counties of England, and in Scotland. It flowers in june and july.

29. Root annual. It is a very different plant from *Craſſula rubens*. Stem an inch high, with two oppoſite branches next the root of the ſame height with the ſtem. Leaves oblong, looſe at the baſe. Peduncles alternate, one-flowered, forming a faſtigiate corymb. Calyxes dark purple. Petals white, ovate, length of the calyx. Stamens ten. Germs dark-purple [u].

30. Native of Madeira, where it was found by Mr. Francis Maſſon, and introduced in 1777. It flowers in july and auguſt [x].]

PROPAGATION AND CULTURE.

The Orpines may be eaſily increaſed by cuttings during the ſummer months, or by parting their roots either in ſpring or autumn; theſe thrive beſt in a dry ſoil and a ſhady ſituation, but may alſo be planted for the ſame purpoſes as the other ſorts, eſpecially the third ſort, which is evergreen. The ſtalks of this kind hang down, and have a very good effect in rock-work, and the plants require no care; for when they are fixed in the place, they will ſpread and propagate faſt enough.

All the ſorts of Stonecrop are eaſily propagated, by planting their trailing ſtalks either in ſpring or ſummer, which ſoon put out roots; but, as theſe thrive much better upon rocks, old walls or buildings, than in the ground, they may be diſpoſed upon rock-work in ſuch a manner as to have a good effect; and where there are unſightly buildings, their tops may be covered with theſe plants ſo as to hide their deformity: in ſuch places, theſe plants will appear to greater advantage than on the ground. If the cuttings or roots of the perennial ſorts are planted in ſome ſoft mud laid upon the walls or buildings, they will ſoon take root, and then ſpread into every joint or crevice, and in a ſhort time will cover the place; or if the ſeeds of thoſe annual ſorts which grow naturally in dry places are ſown ſoon after they are ripe on the top of walls, the plants will come up, and maintain themſelves without farther care.

Stem ſcandent unarmed, leaves ovate quite entire, racemes long, axillary and terminating.

DESCRIPTIONS, &c.

1. This is a ſhrub about twelve feet in height, with very long, round, green, ſhining branches, by which it ſupports itſelf. Prickles recurved, acuminate, very ſhort, ſingle on each ſide of the petiole; but ſometimes wanting. Leaves lanceolate ovate or oval, emarginate with a point, entire, ſhining, petioled, alternate, two or three inches long. Racemes terminating, branched, leafy. Flowers numerous, whitiſh, ill-ſcented. The calyx with the increaſing germ becomes green. The unripe fruit is like that of Securidaca.

Native of South America, about Carthagena in woods and coppices, eſpecially by way-ſides; flowering in ſeptember [y].

2. Stem ſhrubby, climbing but without tendrils, branched, round, long, not thick, very tough and fit for binding. Leaves alternate, rough, on ſhort petioles. Flowers greeniſh-white, void of ſcent. Calyx corolline, of five roundiſh concave ſpreading leaflets. Filaments ſhorter than the calyx. Style ſtill ſhorter, with a thickiſh ſtigma. Capſule ovate, acuminate, red, two-valved. Seed roundiſh, pedicelled, connected by a large many-cleft wing, the ſegments of which are linear; but it has not any lateral little wings at the baſe. Native of Cochinchina, in woods [z].

Lippia ovata. *Lin. mant.* 89. *& Dict. noſtr.*
Spikes ſtrobiline ovate terminating, leaves ſcattered linear, ſtem ſhrubby.

DESCRIPTIONS, *&c.*

Theſe plants are herbaceous or ſhrubby, all natives of the Cape of Good Hope. Leaves alternate. Flowers in moſt of the ſpecies allied to thoſe of *Eranthemum* and *Verbena*, irregular, tubular, in alternate terminating ſpikes, which are ſimple or manifold: in a few, the flowers are regular, with a ſhort two-ſeeded tube, in a ſort of terminating corymb [a].]

1. Stems ſlender woody, riſing ſeven or eight feet high, but ſo weak as to require ſupport: they ſend out many ſlender branches. Leaves ſhort, linear, hairy, coming out in cluſters. Flowers ſmall, and of a pure white; appearing in july and auguſt, but not followed by ſeeds in England.

This plant is preſerved in gardens more for the ſake of variety than beauty: for the branches grow very irregular and hang down, and both leaves and flowers are ſmall.

[The fruit is ſaid to have two ſeeds in it [b]. It was cultivated in 1759, by Mr. Miller [c].

2. Stem fruticoſe, erect, even, branched, half a foot high. Leaves in cluſters at each germ, linear, ſomewhat rigid, naked, twice as thick as, and ſhorter by half than in the preceding. Corymb terminating, as in that: the ſpikes having a ſmall hiſpid calyx; the corollas being white; and the fruits ovate, bipartile into two ſeeds [d].

3. Border of the corolla four-parted, with the two outer ſegments larger [e].

4. Stem ſuffruticoſe. Leaves like thoſe of *Hebenſtreitia dentata*, alternate, cluſtered. Spike ovate-oblong, blunt, cloſely imbricate; with oblong, membranaceous bractes. Corollas five-cleft, violet; with a long filiform tube. Capſule ſix-valved [f]. Introduced in 1786, by Mr. Francis Maſſon. It is biennial, and flowers in june [g].

5. Stem quite ſimple, erect, even, two feet high. Leaves alternate, oblong, even, acutely ſerrate except at the baſe where they are quite entire and very ſlightly decurrent. Corymb terminating, cloſe. Calyx with five awl-ſhaped teeth, length of half the tube of the corolla. Corolla purple. Stigma blunt [h]. Introduced in 1774, by Maſſon. It is biennial and flowers in june [i]. Seeds two, ſmall, oblong, convex on one ſide, excavated with a groove on the other, brown, clothed by the calyx [k].

6. This much reſembles the *rapunculoides*, but the leaves are thicker and ſmooth; the lower ones not at all toothed. Stems from the root ſeveral, a foot high, quite ſimple. Corollas very deep purple, with the outer ſegment larger [l].

7. Stem ſuffruticoſe, erect, pubeſcent. Leaves blunt, ſmooth, like thoſe of *S. corymboſa*, but thicker. Spike ſubovate, cloſe, ſolitary, imbricate with bractes and flowers. Bractes rhombed, ſcarioſe, length of the flowers.

8. This is a lofty ſhrub with unequal branches. Leaves ſmall, unequal, in cluſters, naked. Heads ſeſſile [m].

9. 10. Found at the Cape by Chevalier Thunberg.

11. The branches in this are more ſpreading and divaricating.

[a] Juſſieu. [b] Linn. ſyſt. [c] Hort. kew. [d] Linn. mant. [e] Linn. ſyſt. [f] Linn. ſpec. [g] Hort. kew. [h] Linn. mant. [i] Hort. kew. [k] Gærtner. [l] Amoen. [m] Linn. mant.

12. 13. Theſe, with the eleventh, were alſo found at the Cape by Thunberg.

14. This has the habit of *Polygala*, with long linear leaves, and pendulous ſpikes.

15. Very like *S. corymboſa*, and perhaps a variety of it.

16. 17. 18. 19. All theſe were found at the Cape by Thunberg.

20. Flowers white, with a yellow ſpot on the two uppermoſt ſegments, and ſometimes on all of them, and an orange ſpot at the mouth of the tube. It is valuable not ſo much on account of its beauty, as the curious ſtructure of its ſpikes, and the fragrancy of its flowers. Linneus deſcribed it from a dried ſpecimen, which accounts for his ſaying that the flowers are of a dark violet-colour. The trivial name of *bracteata* would have been better than *ovata*; for though its ovate inflorescence may be peculiar to the ſpecies, its bractes are ſo very ſingular, that they conſtitute the moſt prominent feature of the plant *.

Like all the reſt it is a native of the Cape, whence it was introduced by Maſſon in 1774. It flowers in june and july °.

Linneus thus deſcribes his *Lippia ovata* in the Mantiſſa.—It is a proſtrate ſhrub, a foot long, with pea-ſhaped knobs all over it, and round branches. Leaves ſomewhat ſucculent, even: from each axil are ſeveral ſmaller leaves, which are ſometimes ternate. Strobiles terminating, ovate, imbricate; with ſcarioſe, ovate, ſmooth bractes, longer than the calyx, reflex at the tip; within each of theſe is a tubular, five-toothed calyx. Corolla funnel-form, five-cleft, dark-violet. Stamens twin, within the tube. Germ one. Style filiform. Stigma ſimple.]

PROPAGATION AND CULTURE.

Plant cuttings, during any of the ſummer months, in a bed of freſh earth, covering them cloſe with a bell or hand-glaſs, ſhading them from the ſun, and refreſhing them now and then with water. Harden them gradually, and then tranſplant them into ſmall pots, placing them in the ſhade till they have taken root. Place them with other hardy greenhouſe plants; and about the end of octobet remove them into the dry ſtove. They only require protection from froſt, and may be treated in the ſame manner with the hardier greenhouſe plants.

Lin. ſpec. ed. Willd. 1. 1400. *Schrad. & Wandl. ſert. hannov.* 3. 23. *t.* 13.
Stem woody naked below, lower leaves bipinnate, pinnules lanceolate entire and gaſhed ſerrate.

DESCRIPTIONS, *&c.*

1. The herb is a little milky, with numerous even ſtems, not ſtriated. Leaflets linear. Umbel patulous. Umbellets remote. Seeds oval-oblong, with three raiſed obtuſe approximating grooves. It has both involucres[p].

Native of Denmark, Germany, Sileſia, France and Piedmont.

2. Root ſubfuſiform, thick, branching, yellowiſh without, white within. The whole plant, when wounded, pours forth a milky thick bitter fetid juice. Stem three or four feet high, ſingle, erect, hollow, deeply grooved, ſmooth, leafy, purple at the bottom, branched at the top. Leaves of a pleaſant green, triangular, in more luxuriant plants upwards of a foot and half in length, and as much or more in breadth, bipinnate or tripinnate; the leaflets oppoſite and pinnatifid; the clefts varying from linear to oval-lanceolate, very entire, reddiſh at the points. Umbels erect, flat, large and beautiful, with many (about thirty) rays. The umbellets have upwards of forty. Involucre and involucret many-leaved, (nine and twelve,) ſhorter than the rays, bent down, membranaceous at the edge. Petals white, involute-cordate, equal: before flowering reddiſh on the outſide. Fruit elliptical, ancipital. Seeds roundiſh, blunt, edged with a kind of border, ſcored in the centre[q].

Native of the North of Europe, Germany, Auſtria, Dauphiné and Piedmont; in ſwamps and moors. Not known to be indigenous of England till very lately. Johnſon (in Gerarde) ſays expreſsly, "I have not as "yet obſerved this plant growing wild with us."—Mr. Hudſon, in the ſecond edition of his Flora Anglica (1778) ſays, it was found near Doncaſter by Mr. Tofield. According to Dr. Withering, it was found in 1779 or 1780, by Mr. Seatle, at Cannon Winder, near Flookburgh in Lancaſhire; and ſince, round the ſides of Ayſide Tarn, three miles north of Cartmell, by Mr. Hall. Brought to Mr. Woodward and Mr. Crowe, when in Lancaſhire in 1781, by the Rev. Mr. Jackſon. In great plenty, in low wet moors near Whitgift, Yorkſhire, four miles from the confluence of the Ouſe and Trent, by Mr. Wood. At Weel Carr, and other wet places near Beverley, by Sir Thomas Frankland. In Alder ſwamps near Yarmouth, by Mr. Wigg. Between Norwich and Heigham towards the river, by Mr. Pitchford. Near Prickwillow bank in the Iſle of Ely, by Mr. Relhan and Dr. Goodenough.—It flowers in july[r].

3. Root perennial, at the beginning of autumn pouring out a moderate quantity of yellowiſh white milk. Stem ſtriated, ſmooth. The radical leaf is divided by a round petiole into three branches, which are again ſubdivided. Petioles ſtriated with eight or ten whitiſh raiſed lines. The ſecond branches bear pinnas that are ſeſſile and divided almoſt to the baſe into lanceolate ſimple bifid and trifid ſegments. Theſe leaves are flat, dark green above and paler beneath: the tips are whitiſh and ending as it were in a ſoft ſpinule. Involucre reflex, ſcarcely half an inch in length, with the leaflets white and as it were membranaceous at the edge. Rays of the umbel as far as twenty-two, ſomewhat villoſe. Involucrets ſpreading. The umbellets have forty rays and upwards. Petals white, equal, cordate. Styles erect, but finally divaricating. All the flowers are not fertile[s].

Native of Auſtria, Idria, and perhaps of Dauphiné and Piedmont. Villars ſuſpects that his plant may be different.

4. Root biennial, fuſiform. Stem erect, three feet high, hollow, ſtriated, glaucous. Leaves tripinnate; pinnas laciniate, acute, white at the tip; petioles compreſſed, channelled above; ſheaths of the upper ones white. Peduncles grooved. Involucre nine-leaved, preſſed cloſe to the rays; leaflets lanceolate, white-membranaceous and pellucid, about half the length of the rays, with a green rib. Involucrets ſimilar, nine-leaved, a little wider and overtopping the flowers. Umbel with from twenty to thirty rays: umbellets with as many white flowers. Seeds with three dorſal ribs beſides the marginal wings, oblong-rounded. It has the ſmell of a freſh Carrot-root; and carries a ſingular appearance on account of the white involucrets entirely involving the umbellets before they are completely unfolded[t]. Retzius received the ſeeds among others from Siberia.

5. Root perennial. Stems acutely ſtriated. All the leaflets have a white apex or dagger-point. Petals converging, concealing the receptacle. Styles erect. Seeds ovate, with three compreſſed ridges, as in *Laſerpitium*: the ſeeds gape from each other at the ſides[u].

Univerſal involucre none; partial many-leaved. Fruit compreſſed, rounded, membranaceous-winged; conſiſting of two ſmall rounded ſeeds, emarginate at top and bottom, five-winged: the two marginal wings very wide and ſpreading; the three dorſal wings narrower by half than the others, approximating nearly upright: the ventral part flat or ſlightly concave[x].

The above deſcription by Gærtner is taken from Gmelin's plant. If we may depend upon Vaillant's (bot. par. t. 5. f. 2.) and Haller's figures, their plant is quite different from this. The figure of the ſeeds in Rivinus and Crantz agrees with that of Gmelin; but the habit of the plant is different: we are to conſider however that moſt of Gmelin's figures are rather in a rough ſtyle[y].

Retzius remarks, that Gmelin's *Selinum* has the leaves of Jacquin's, but ſmaller, and in the figure, the long wide ſheaths, ſimply pinnate at the end, are wanting; it rather belongs however to this, than to the *caruifolia* of Linneus. In the *caruifolia* of Crantz, the conformation of the ſheaths is the ſame as in Jacquin's, but the leaves are diſſimilar.

Retzius affirms that three diſtinct plants have been confounded under the name of *caruifolia.*

1. *Selinum caruifolia* of Linneus, Haller and Flora Danica.

2. *Sel. Caruifolia* of Jacquin.

3. *S. Caruifolia* of Crantz. See the next ſpecies.

Native of Denmark, Germany, Switzerland, Auſtria and Siberia. Introduced in 1774, by Monſ. Richard. It flowers in july and auguſt[z].

6. Height from eight inches to a foot. Stems ſmooth, channelled, ſupporting two or three umbels. Root-leaves very much reſembling thoſe of *Carui*, but not quite ſo fine: leaflets branched, unequal, and diſpoſed ſo as to form ſeveral croſſes round the common petiole: ſtem-leaves very different, being ſimply pinnate, with ſome forked leaflets at their baſe, rendering them bipinnate; the ſegments four or ſix times as long as in the root-leaves: thus approaching to Peucedanum, and deſtroying all reſemblance between this plant and that figured by Vaillant in *t.* 5. *f.* 2. which Crantz has referred to this. The umbels have ſometimes an involucre of ſeveral very narrow leaves, but frequently are without any: they have eight or ten unequal rays: the umbellets have an involucre of ſeveral leaves. Seeds a little oblong, with a marginal wing, and three apparent ribs, but not riſing much, on the back. This ſpecies is intermediate between *Peucedanum* and *Selinum*[a].

Native of Germany, Auſtria, France and Italy.

7. Stem manifold, four feet high, even, not ſtriated except at the top, where it is very obſcurely ſo. Upper branches oppoſite, as are alſo the leaves. Leaves tripinnate,

[p] Linn. mant. [q] Smith and Woodw. in Withering. [r] Smith and Withering. [s] Scopoli. [t] Retzius [u] Lin. ſyſt. mant. ſuppl. [x] Gærtner. [y] Idem. [z] Hort. kew. [a] Villars.

Digitized by Google

tripinnate, ſpreading; partial ones divaricate or ſpreading very much. Pinnas linear, acute, ſeſſile, ſubdecurrent, with an unarmed point. Umbel compound, with rays as far as forty. Umbellet with many rays. Common peduncle indiſtinctly ſtriated. Involucre none. Involucrets briſtle-ſhaped, many, ſhorter than the florets. Corollas expanded. Petals white. Styles of the fruit ſpreading horizontally. Perennial.

Native of Italy and Carniola [b]. Introduced in 1774, by Joſeph Nicholas de Jacquin, M. D. It flowers in july [c].

8. This has the ſame ſtructure of the ſeeds as in *Laſerpitium*; but the habit and every thing elſe of *Selinum* [d]. Stem ſometimes purpliſh, with very numerous ſtreaks. Peduncles oppoſite to the leaf, ſtriated alſo, thicker at the top. Involucre of ſeven or nine unequal briſtle-ſhaped leaflets, ſcarcely two lines long. Involucrets of ſeven or nine briſtle-ſhaped leaflets, the length of the pedicels or umbellets. Hairs on the branches and upper part of the ſtem few; towards the bottom and on younger plants more abundant. In a garden the plant becomes frequently quite ſmooth [e].

Native of the South of France. Annual. Flowering in july and auguſt. Introduced in 1771, by Mr. Richard [f].

9. Stem the thickneſs of the thumb, below woody and naked. Leaves almoſt like thoſe of *Angelica*, wide and bipinnate; leaflets lanceolate, ſerrate, the end one gaſhed; floral leaves pinnate, with the end and lower leaflets gaſhed. Sheaths widened, toothed. Involucre many-leaved; leaflets wide, lanceolate-cuneiform, trifid, membranaceous at the edge. Involucrets many-leaved, lanceolate [g].]

PROPAGATION AND CULTURE.

Theſe plants are eaſily propagated by ſeeds, ſown in the autumn. The plants are to be treated in the ſame way as Angelica.

DESCRIPTION, *&c.*

This is a large tree, with a great, ſtraight, lofty trunk, covered with gray ſcabrous bark: the bark of the younger parts is ſmooth, and of a light aſh-colour; its inner ſubſtance contains in crevices a quantity of a white, ſoft, almoſt inſipid gum. Branches numerous, ſpreading. Leaves about the extremities of the branchlets, alternate, petioled, wedge-form, rounded at the apex, entire, firm, above pretty ſmooth, below whitiſh and ſcabrous, from nine to eighteen inches long, and from four to eight broad. Petiole an inch and half or two inches long, half-round. Panicle terminating, very large, compoſed of many ſimple ſpikes; that of the male tree much more ſlender, but as large or larger. Bractes many, ſmall, falling. Flowers numerous, ſmall, of a dirty-greeniſh yellow colour. Receptacle of the fruit, when ripe, yellow, about the ſize of the nut; which is black; the cover or ſhell compoſed of two laminæ, the inner hard, the outer leſs ſo and leathery; between them are cells, which contain the black corroſive reſinous juice, for which this nut has been long known; the juice is of a pale milk colour, till perfectly ripe, when it becomes black.

It is a native of all the mountainous parts of India; flowering in july and auguſt. The ſeed is ripe in january and february.

The wood of this tree is reckoned of no uſe, not only on account of its ſoftneſs, but alſo becauſe it contains much acrid juice, which renders it dangerous to cut down and work upon. The fleſhy receptacles on which the ſeed reſts are roaſted in the aſhes, and eaten by the natives: their taſte is exceedingly like that of roaſted apples: unroaſted they taſte aſtringent and acrid, leaving a painful ſenſation on the tongue for ſome time. The kernels are rarely eaten.

The green fruit well pounded into a pulp makes good bird-lime. The pure black acrid juice of the ſhell is employed by the natives externally, to remove rheumatic pains, aches and ſprains; in tender conſtitutions it often produces inflammation and ſwelling; but where it has not theſe effects, it is an efficacious remedy. It is employed by the Telinga phyſicians in the cure of almoſt every ſort of venereal complaint.

It is in general uſe for marking cotton cloths; the colour is improved and prevented from running, by a little mixture of quick-lime and water. This juice is not ſoluble in water, and only diffuſible in ſpirits of wine, for it ſoon falls to the bottom, unleſs the menſtruum be previouſly alkalized. The ſolution is then pretty complete, and of a deep black colour. It ſinks in expreſſed oils, but ſoon unites perfectly with them: alkaline lixivium acts upon it with no better ſucceſs than plain water [h].

Leaves round-club-ſhaped cluſtered, pedunclas naked moſtly one-flowered, nectaries obcordate.]

DESCRIPTIONS, &c.

1. Tree Houſeleek riſes with a fleſhy ſmooth ſtalk eight or ten feet high, dividing into many branches, which are terminated by round heads or cluſters of leaves lying over each other like the petals of a double Roſe, ſucculent, of a bright green, and having very ſmall indentures on their edges. The ſtalks are marked with the veſtiges of the fallen leaves, and have a light brown bark. The flower-ſtalks riſe from the centre of theſe heads; and the numerous bright-yellow flowers form a large pyramidal ſpike, or thyrſe.

[Each flower is pedicelled, and is accompanied by a lanceolate, acute bracte, which ſhrivels and falls off. Calyx ten-parted. Petals ten. Scales of the nectary as many at the baſe of the filaments. Stamens twenty. Germs ten, with a gland at the baſe of each[1].

Native of Portugal, the Levant, and Barbary near Algiers:] the old walls about Liſbon are covered with it. It flowers through the winter, commonly from

[1] Linn. and Desfont.

Digitized by Google

december to march. [Cultivated here in 1727, as appears from Bradley's ſucculent plants[k].]

A variety of this with variegated leaves was obtained from a branch accidentally broken from a plant of the plain ſort, at Badmington, the ſeat of the Duke of Beaufort. [This plant therefore muſt have been cultivated here long before Bradley's time.]

2. This ſeldom riſes above a foot and half high, unleſs the plants are drawn up by tender management. The ſtalk is thick and rugged, chiefly occaſioned by the veſtiges of decayed leaves. At the top is a very large crown of leaves, diſpoſed circularly like a full blown Roſe: they are large, ſucculent, ſoft to the touch, and pliable, ending in obtuſe points which are a little incurved. The flower-ſtalk comes out from the centre, and riſes near two feet high, branching out from the bottom, ſo as to form a regular pyramid of flowers, which are of an herbaceous colour.

[Petals nine. Stamens eighteen. Piſtils nine.—Native of the Canary Iſlands. Cultivated in 1699, by the Dutcheſs of Beaufort. It flowers in june and july.

3. Petals yellow, eight or nine. Stamens ſixteen or eighteen. Piſtils eight or nine.—Native of Madeira; whence it was introduced by Maſſon in 1777. It flowers in july and auguſt.

4. This alſo is native of Madeira; and was introduced at the ſame time with the former by Maſſon. It flowers from march to may[l].

5. Common Houſeleek has a perennial fibrous root. Root-leaves in form of a full-blown double Roſe, ſeſſile, wedge-ſhaped or obovate, ſomewhat more than an inch long, very fleſhy, thick, flat above, a little convex beneath keeled and whitiſh, ſmooth on both ſides, the edges fringed with hairs and generally tinged with red, pointed, upright, gradually ſmaller inwards. Offsets on long footſtalks, globular, the ſize of a pigeon's egg or larger, compoſed of erect leaves lying over each other. Flowering-ſtem upright, from nine inches to a foot in height, round, fleſhy, pubeſcent, having alternate, lanceolate, thinner leaves on it, of a reddiſh colour, at top branched and forming a ſort of corymb; the branches ſpreading and bending back. Flowers numerous, cluſtered, upright, pubeſcent, fleſh-coloured, all growing one way. Calyx twelve-parted (12 to 16. *H.*): ſegments lanceolate, hirſute, ciliate, clammy, purpliſh at top. Petals twelve or more, twice the length of the calyx, lanceolate, connate at the baſe. Stamens ſhorter than the petals, generally fourteen; (6 to 25. *W.* 24 to 32. *H.*) but varying in length and number, as indeed all the parts do. Germs twelve, upright[m]. Capſules twelve to ſixteen[n].

Haller, who has minutely deſcribed this plant, as he found it in its wild ſtate on the Alps, remarks that the filaments are of two kinds, the one perfect and ſimilar to the generality of filaments, the other even when young evidently enlarged towards the end, and throwing out from their ſubſtance little oblong white corpuſcles, like the eggs of ſome inſect. Mr. Curtis farther remarks, that the filaments thus enlarged are more glutinous than the others, and the anthers ſomewhat imperfect; as the fructification proceeded towards maturity, the filaments continued to enlarge about the middle, while the top was drawn out to a kind of beak, and in this ſtate they ſeem to partake more of the nature of the piſtil than the filaments: on cutting them through they appeared hollow, and contained ſome of the ſame corpuſcles which were obſervable on the outſides of many of them[o].

Native of ſome parts of Europe on rocks; it is common in moſt parts on the roofs of buildings, but there not properly indigenous, though inſerted in all the Floras. It flowers in july.

The juice, either applied by itſelf, or mixed with cream, gives preſent relief in burns, and other external inflammations. With honey, it is a uſeful application in the thruſh[p].

Boerhaave found ten ounces of the juice beneficial in dyſenteries, and others have found it uſeful in gonorrhœas[q]: but it is not admitted into our modern practice.

Linneus informs us, that Houſeleek is a preſervative to the coverings of houſes in Smoland. It may eaſily be made to cover the whole roof of a building, whether of tiles, thatch or wood, by ſticking the offſets on with a little earth or cow-dung[r].

It had ſeveral names in Engliſh formerly, as Sengreen and Aygreen, both tranſlations of *Sempervivum*; Jupiter's eye, Bullock's eye, and Jupiter's beard[s]. Withering gives it another name, *Cyphel*, which I never heard of.—In German it is *Hauſwurz*; in French, *la grande Joubarbe*; in Italian, *Sempervivo maggiore*.]

6. Leaves much narrrower, and the heads furniſhed with a greater number of them than thoſe of the preceding ſpecies, which grow more compact, and are cloſely ſet on their edges with hairs. The offsets of this are globular, their leaves turning inward at the top, and lying cloſe over each other: theſe are thrown off from between the larger heads, and falling on the ground, take root, whereby it propagates very faſt. The flower-ſtalks of this are ſmaller, and do not riſe ſo high as thoſe of the former; and the flowers are of a paler colour.

According to Jacquin, the flowers have ſix petals, ſix ſtamens, and ſix piſtils. Haller ſays that the calyx is divided into twelve parts; that the corolla has twelve petals, which are united at the baſe, pale yellow, hairy, ciliate, long and ſlender; that the ſtamens are half the length of the petals; and that the capſules are ſmooth, and ſomewhat fewer in number than the petals.—Villars cannot diſtinguiſh the *globiferum* of Linneus from the *montanum* of the ſame author.

Native of Ruſſia, Auſtria, Germany, Switzerland. Cultivated in 1731, by Mr. Miller. It flowers in june and july.

7. Petals eight, yellow; ſtamens from twelve to ſixteen; piſtils eight. It is an annual plant, native of Madeira, where it was found by Maſſon, and introduced in 1777. It flowers in june[t].

8. This is a ſhrubby plant of low growth, producing numerous fleſhy leaves, growing thickly together. It throws up its flowering-ſtems, ſupporting numerous yellow flowers, like thoſe of *Stonecrop*, in july and auguſt[u]. Petals eight. Stamens ſixteen. Piſtils eight.

Native of the Canary Iſlands, where it was diſcovered by Maſſon, and introduced in 1779. It flowers in july and auguſt[x].

9. This whole plant is, as it were, a repreſentation in miniature of *Sempervivum arboreum*, but more lax and diffuſe. It is abundandy diſtinguiſhed from that ſpecies by its annual root, herbaceous pubeſcent ſtem, and ſpreading panicle. The flowers are yellow, and agree perfectly with the generic character of *Sempervivum*; not with that of *Sedum*.

If the ſynonym of Seguier be right, it is a native of Monte Baldo, where it was found on the rocks by Giovanni Battiſta Scarella. It has been long cultivated in the garden of the Company of Apothecaries at Chelſea, and flowers there every year, but whence it was brought is not known.

It is extremely different from the *Sedum alſinæfolium* of Allioni; but may perhaps be the *Sempervivum alpinum Montis Baldi, foliis lenticulatis, floribus non punctatis*, of Mauritius Hoffman, mentioned by that author in his *Specimen pedemontanum*, *p.* 16[y].]

10. This has much ſhorter and narrower leaves than the common Houſeleek. The heads are ſmall and very compact. Leaves gray, ſharp-pointed, and have ſlender white threads croſſing from one to the other, interſecting each other in various manners, ſo as in ſome meaſure to reſemble a ſpider's web. Flower-ſtalks about ſix inches high, ſucculent and round, having awl-ſhaped ſucculent leaves placed on them alternately: the upper part divides into two or three branches, upon each of which is a ſingle row of flowers ranged on one ſide; each compoſed of eight lanceolate petals, of a bright red colour, with a deep-red line running along

[k] Hort. kew. [l] Idem. [m] Curtis and Smith. [n] Haller. [o] Hall. helv. and Curt. lond. [p] Withering.

[q] Haller. [r] Curtis. [s] Gerarde. [t] Hort. kew. [u] Curtis. [x] Hort. kew. [y] Smith, in Linn. tranſ.

Digitized by Google

the middle: they ſpread open in form of a ſtar, and in the centre are the germs of an herbaceous colour, ſurrounded by ſixteen purple filaments, terminated by yellow anthers.

[Haller who regards this as very nearly allied to the *montanum*, attributes nine petals to the flowers.

Native of the mountains of Switzerland, Dauphiné and Italy. Cultivated in 1699 by the Dutcheſs of Beaufort. It flowers in june and july [z]; and is commonly known by the name of *Cobweb Sedum*, it is however clearly a *Sempervivum* in habit as well as fructification [a].

11. Root hard, round, perennial; from which there are many roſe-like tufts of leaves, as in the next ſpecies. Leaves finely hairy, eſpecially about the edges. Stem round, hairy, with long ſharp ſcales, thicker ſet towards the top; the upper part divided into ſeveral branches, bearing each two or three erect flowers, beſides a ſingle one ſeſſile in the diviſion of the branches. Petals ſix, twice as long as the calyx, keeled, whitiſh, entire, of a very long elliptic form, fringed at the edge, with the end ſtill more deeply cut into fringes; the keel eſpecially is very finely hairy. Stamens twelve, with awl-ſhaped hairy filaments, and four-grooved anthers. Piſtils ſix, a little ſhorter than the petals [b].—Native of Germany, Sileſia, Piedmont.]

12. This greatly reſembles the fifth or common Houſeleek, but the leaves are ſmaller, and have no indentures on their edges. The offsets ſpread out from the ſide of the older heads, and their leaves are more open and expanded. Flower-ſtalk nine or ten inches high, having ſome narrow leaves below; the upper part is divided into three or four branches, cloſely ſet with deep-red flowers compoſed of twelve petals, and twenty-four ſtamens with purple anthers.

[Villars ſays the leaves are narrower and more pubeſcent beneath than in the common ſort, and a little clammy; the whole plant has leſs conſiſtence; the petals and filaments are roſe-coloured.

Gerard diſtinguiſhes between this and the *arachnoides*, that in the latter the tufts of leaves are contracted and furniſhed with long hairs; whereas in the former (our montanum) the tufts of leaves are expanded, and have no hairs.

Calyx twelve-cleft. Petals connected at bottom. Stamens twelve. Capſules twelve to ſixteen, membranaceous, diſpoſed in a wide ring, curved like an S, beaked. Seeds very numerous and minute, oblong, roundiſh, ſmooth, ruſeſcent, faſtened in ſeveral rows to the margin of the future [c].

Native of Germany, Sileſia, Auſtria, Switzerland, the South of France, and Italy. Cultivated in 1759, by Mr. Miller. It flowers in june and july [d].

13. All the ſtems are perpetually and conſtantly very ſtiff and ſtanding upright. Petals whitiſh [e].—Native of the South of Europe. Introduced in 1769, by Meſſrs. Kennedy and Lee. It flowers in july [f].

β. Jacquin, in his miſcellanea, deſcribes a monſtrous variety of this, with the ſtem terminating in three racemes, two of which are bifid a little above the baſe; and beyond the flowers they are produced into leafy branches which attain three inches in length: ſome of the flowers have fourteen petals.

Linneus had ſuppoſed that this *Sempervivum* of Jacquin was the ſame with his *Sedum rupeſtre:* but Jacquin had cultivated them during twenty years cloſe together, and among others remarks three principal differences: 1. That in *Sedum rupeſtre* the leaves are gradually attenuated into a ſharp point, which is not the caſe in this *Sempervivum*. 2. That the petals in that Sedum are yellow; but in this whitiſh. 3. That all the ſtems, as before obſerved, from firſt to laſt, are perfectly ſtiff and upright; whereas in *Sedum rupeſtre* the upper part of the ſtem, until it is quite in flower, is very much incurved and nods [g].

Native of the South of Europe. Introduced in 1769, by Meſſrs. Kennedy and Lee. It flowers in july [h].

[a] Hort. kew. [b] Curtis. [c] Allioni. [d] Gærtner. [e] Hort. kew. [f] Jacquin. [g] Jacqu. miſc. [h] Hort. kew.

14. The number of the parts of fructification varies from five to eight [i].—In the ſpecimens which Mr. Curtis examined, rendered perhaps luxuriant by culture, the number of ſtamens were from twelve to ſixteen; of ſtyles, from ſix to eight; of flowers on the ſame ſtalk, from one to eight. The nectaries form a principal part of the fructification, and are uſually ſeven in number, but vary from ſix to eight [k].

Native of the Canary Iſlands: whence it was introduced by Maſſon in 1777. It flowers in july [l], and during moſt of the ſummer months [m].]

PROPAGATION AND CULTURE.

1. This is eaſily propagated by cutting off the branches, which, when planted, ſoon put out roots; theſe ſhould be laid in a dry place for a week before they are planted, that the bottom may be healed over, otherwiſe they are apt to rot, eſpecially if they have much wet. When the cuttings are planted in pots, they ſhould be placed in a ſhady ſituation, and muſt have but little wet, and if they are planted in a ſhady border, they will require no water, for the moiſture of the ground will be ſufficient for them. Some years paſt theſe plants were tenderly treated; their cuttings were put into a hot-bed to forward their putting out roots, and in winter the plants were kept in ſtoves, but later experience has taught us that they will thrive better with hardier treatment; for, if they are protected from froſt and wet in winter, and have a good ſhare of air in mild weather, they will thrive better, and flower oftener than when they are tenderly nurſed. I have frequently ſeen the branches of theſe plants, which have been accidentally broken off and fallen on the ground, put out roots as they have laid, and make good plants. The variety with ſtriped leaves is more tender and impatient of wet in winter.

2. This is propagated by ſeeds, which ſhould be ſown ſoon after it is ripe in pots filled with light ſandy earth, covering them over very lightly with the ſame earth. Theſe pots ſhould be placed under a common frame to keep out the froſt, but ſhould be expoſed to the open air at all times in mild weather; here the pots may remain till the ſpring, when the danger of hard froſts is over, and then they ſhould be removed to a ſituation where they may have only the morning ſun, and in dry weather the earth ſhould be watered gently. This will ſoon bring up the plants, which muſt be kept clean from weeds, and, when they are fit to remove, they ſhould be planted in pots filled with light loamy earth, and placed in the ſhade till they have taken new root; then they may be placed with other hardy ſucculent plants in a ſheltered ſituation for the ſummer, and if in winter they are placed in a frame where they may be protected from hard froſt, and enjoy the free air in mild weather, they will thrive better than with tender treatment.

5. 6. 9. 10. 11. 12. 13. Theſe ſorts are hardy, and increaſe faſt by offsets: they love a dry ſoil, and are proper to plant on rock-work, where they will thrive better than in the full ground: and when they are once fixed, will ſpread faſt enough, inſomuch that the larger ſorts require to be reduced annually, to keep them within proper compaſs. When any of the heads flower, they die ſoon after; but the offsets ſoon ſupply their place.—If the common ſort, (n. 5.) be planted in mud, ſtrong earth, or cow-dung, on a building or old wall, it will thrive without farther care.

[3. 4. 7. 8. 14. Require the protection of a dry ſtove or greenhouſe in winter. N. 8. is readily propagated by cuttings. N. 3. and 4. may be increaſed the ſame way. N. 7. is propagated by ſeeds: and n. 14. by parting the roots. This, and n. 3, 4. will ſucceed with the common treatment of a greenhouſe plant in the ſummer, but do beſt in a dry ſtove during the winter.

SENA. See *Caſſia, Colutea, Coronilla, Poinciana.*

SENDERA CLANDI. See *Evolvulus.*]

SENECIO (*of Pliny. From* Senex, *an old man; or* ſeneſcere, *to grow old; the flowers going off early, and producing their ſeeds crowned with a down, like gray hairs.*)

[i] Idem. [k] Curtis. [l] Hort. kew. [m] Curtis.

Lin.

Lin. gen. n. 953. *Reich. n.* 1033. *Schreb. n.* 1290. *Tournef. t.* 260. *Dill. elth. t.* 258. *Vaill. act. gall.* 1719. *Juss.* 181. *Gærtn. t.* 166. Jacobæa. *Tournef.*

Class. 19. 2. Syngenesia Polygamia Superflua.

Nat. order of *Compositæ Discoideæ. Corymbiferæ*, Juss.

GENERIC CHARACTER.

CAL. *Common* calycled, conical, truncate: *scales* awl-shaped, very many, parallel in a cylinder contracted above, contiguous, equal, fewer covering the base imbricatewise, the tops mortified.

COR. *Compound*, higher than the calyx. *Corollets* hermaphrodite, tubular, numerous in the disk. *Females* ligulate in the ray, if any present.

Proper in the hermaphrodites funnel-form: *border* reflex, five-cleft.

In the *females*, if any, oblong, obscurely three-toothed.

STAM. in the hermaphrodites, *Filaments* five, capillary, very small. *Anther* cylindric, tubular.

PIST. in both. *Germ* ovate. *Style* filiform, length of the stamens. *Stigmas* two, oblong, revolute.

PER. none. *Calyx* conical-converging.

SEEDS in the hermaphrodites solitary, ovate. *Pappus* capillary, long. In the *females* very like the hermaphrodites.

REC. naked, flat.

OBS. Senecio, Tournef. *wants the common ray of the corolla.*

Jacobæa, Tournef. *is furnished with the common ray of the corolla.*

ESSENTIAL CHARACTER.

Cal. cylindrical, calycled, with the scales mortified at the tip. *Down* simple. *Recept.* naked.

SPECIES.

* *With floscules flowers.*

1. Senecio hieracifolius. *Hieracium-leaved Groundsel.*
Lin. spec. 1215. *syst.* 756. *Reich.* 3. 788. *hort. upsal.* 261. *cliff.* 406. *mant.* 469. *Herm. par. t.* 226. *Pluk. phyt. t.* 112. *f.* 1.
Corollas naked, leaves embracing lacerate, stem herbaceous erect.

[2. Senecio purpureus. *Purple Groundsel.*
Lin. spec. 1215. *syst.* 756. *Reich.* 3. 788. *Berg. cap.* 276. *Breyn. cent.* 139. *t.* 67.
Corollas naked, leaves lyrate rough-haired, the upper ones lanceolate toothed.

3. Senecio erubescens. *Blush-coloured Groundsel.*
Ait. kew. 3. 190.
Corollas naked, leaves lyrate, on both sides hairy clammy, the upper ones oblong-lanceolate toothed, stems ascending.

4. Senecio cernuus. *Drooping Groundsel.*
Lin. syst. 756. *suppl.* 370.
S. rubens. *Jacqu. hort.* 3. 50. *t.* 98.
Corollas naked, leaves elliptic tooth-serrate somewhat hairy, peduncles elongated one-flowered.

5. Senecio perficifolius. *Peach-leaved Groundsel.*
Lin. spec. 1215. *Reich.* 3. 789. *amoen.* 6. *afr.* 62.
Corollas naked, leaves lanceolate quite entire toothed at the base.

6. Senecio virgatus. *Twiggy Groundsel.*
Lin. spec. 1215. *Reich.* 3. 789. *amoen.* 6. *afr.* 63.
Corollas naked, leaves lyrate tomentose underneath, peduncles one-flowered, scales awl-shaped.

7. Senecio divaricatus. *Straddling Groundsel.*
Lin. spec. 1215. *Reich.* 3. 789. *Lour. cochinch.* 502. *ed. Willd.* 613.
Corollas naked, leaves lanceolate toothed rugged, flowering branchlets divaricating.]

8. Senecio Pseudo-China. *Chinese Groundsel.*
Lin. spec. 1216. *Reich.* 3. 789. *Dill. elth.* 345. *t.* 258. *f.* 335.
Corollas naked, scape almost naked very long.

[9. Senecio reclinatus. *Grass-leaved Groundsel.*
Lin. syst. 756. *suppl.* 369. *L'Herit. stirp. nov.* 9. *t.* 5. *Ait. kew.* 3. 189.
S. Cherysocoma. *Meerb. ic.* 39.
S. graminifolius. *Jacqu. icon. rar.* 3. *t.* 66. & *misc.* 2. 322.
Corollas naked, calyxes ventricose, subimbricate, leaves filiform-linear quite entire smooth.

10. Senecio vulgaris. *Common Groundsel.*

Verbena fœmina. *Brunf. herb.* 1. 120.
Corollas naked, leaves pinnatifid sinuate embracing, flowers scattered.

11. Senecio bifiorus. *Two-flowered Groundsel.*
Vahl symb. 1. 72.
S. linifolius. *Forsk. arab.* 119. *n.* 502.
Corollas naked, leaves linear flat somewhat toothed even, peduncles subbifiorous, stem shrubby.

12. Senecio arabicus. *Arabian Groundsel.*
Lin. syst. 756. *Reich.* 3. 790. *mant.* 114. *Vahl symb.* 1. 72.
Corollas naked, leaves subbipinnate petioled even.

13. Senecio peucedanifolius.
Lin. syst. 756. *suppl.* 372.
Corollas naked, leaves pinnate filiform.

14. Senecio japonicus. *Jagged-leaved Groundsel.*
Lin. syst. 756. *Thunb. jap.* 315.
Corollas naked, leaves pinnatifid: segments lanceolate acute gashed, stipules leafy subpalmate.

** *Flowers radiate: ray revolute.*

15. Senecio trifiorus. *Three-flowered Groundsel.*
Lin. spec. 1216. *Reich.* 3. 790. *hort. upsal.* 261. *Willich obs. n.* 130. *Kniph. cent.* 1. *n.* 80.
Jacobæa ægyptiaca, senecionis folio semifloculis vix conspicuis. *Vaill. act.* 1720. *p.* 298.
Corollas revolute, leaves sessile sinuate, calyxes conical, scales very small untouched.

16. Senecio ægyptius. *Egyptian Groundsel.*
Lin. spec. 1216. *syst.* 756. *Reich.* 3. 790. *hort. upsal.* 261. *mant.* 517.
Jacobæa ægyptiaca, senecionis folio, flore minore. *Vaill. act.* 1720. *p.* 298.
Corollas revolute, leaves embracing sinuate, scales of the calyx shorter entire mortified.

17. Senecio cinerascens. *Gray Groundsel.*
Ait. kew. 3. 191.
Corollas revolute, leaves pinnatifid tomentose rolled back at the edge, panicle patulous, outer scales of the calyx spreading.

18. Senecio lividus. *Livid Groundsel.*
Lin. spec. 1216. *Reich.* 3. 791. *hort. upsal.* 261. *Kniph. cent.* 10. *n.* 79.
Corollas revolute, leaves embracing lanceolate toothed, scales of the calyx very short untouched.

19. Senecio trilobus. *Three-lobed Groundsel.*
Lin. spec. 1217. *Reich.* 3. 791. *hort. upsal.* 261.
Jacobæa hispanica minus laciniata, petalis brevissimis. *Vaill. par.* 21.
Corollas revolute, leaves embracing, scales of the calyx mortified lacerated.

20. Senecio viscosus. *Sticking Groundsel.*

Corollas radiant, leaves embracing lanceolate ſomewhat toothed even.]

DESCRIPTIONS, &c.

1. This is an annual plant, with a round, channelled, hairy ſtalk, riſing three feet high. Flowers in a ſort of terminating umbel, compoſed of dirty-white florets.

[Stem a foot and half high, thick, rigid, leſs panicled than the reſt. Stem-leaves lanceolate, ſubſerrate, nodding; branch-leaves quite entire. Calyx imbricate with erect leaflets, the length of the ray. Diſk of the corolla ovate, with ſmall pale florets, and a yellow ſtyle. Ray poor, white and very ſhort [a].

Native of North America. Cultivated by Mr. Miller in 1752. It flowers in auguſt.

2. Native of the Cape of Good Hope. Perennial.

3. This alſo is a native of the Cape, where it was found by Maſſon, and introduced with the preceding, in 1774. It is annual, and flowers from june to october [b].

4. Stem a foot high, upright, herbaceous. Leaves alternate, petioled, veined, rugged, roſe, and as it were ſtipuled, with two angular earlets. Peduncles from the upper part of the ſtem, long, before the flower opens drooping and as it were pendulous. Flowers violet-coloured, upright after flowering. Calyx cylindrical, ſwelling at the baſe, girt with awl-ſhaped leaflets.

Native of Madagaſcar [c]:—of the Eaſt Indies. Introduced in 1780, by Monſ. Thouin. It flowers in july and auguſt; and is annual [d].

5. Stem ſimple, a little villoſe. Leaves ſeſſile, acuminate, tomentoſe underneath. Flowers in terminating corymbs. Calyx calycled.

6. This is ſuffruteſcent, with tomentoſe branches. Leaves petioled. Peduncles terminating, even, ſtraight, long, having awl-ſhaped leaflets (or ſcales) ſcattered over them. Both are natives of the Cape of Good Hope [e].

7. Stem erect, angular, narrow, a foot and half high. Leaves alternate, remote, petioled, ſerrate-toothed, to-

[a] Linn. mant. [b] Hort. kew. [c] Linn. ſuppl. [d] Hort. kew. [e] Linn. amoen.

mentoſe-

mentoſe-rugged. Rudiments only of branches from the axils of the leaves. From the uppermoſt however of theſe are a few branchlets with flowers, very much divaricated at the baſe. Flowers terminating, few, peduncled, the ſame ſize as in the firſt ſpecies; the calyxes having a few looſe awl-ſhaped ſcales ſcattered over them at the baſe.

Found in China by Oſbeck [f]; and alſo by Loureiro near Canton.]

8. Root perennial, compoſed of ſome thick fleſhy tubers, ſending out many fibres on every ſide; from which come out ſome large cut leaves ſhaped like thoſe of the Turnep, but ſmooth. Flower-ſtalk ſlender, a foot and half high, ſuſtaining at the top a few yellow flowers.

[Native of the Eaſt Indies. Cultivated in 1732 by James Sherard, M.D.[g]—In the *Hortus Elthamenſis*, publiſhed in 1732, Dillenius ſays that this plant had then flowered many years in that garden; and that it was firſt ſent over by Sam. Brown, with the country name of *Paring-Chekka*.

9. Stem woody, erect, three feet high, the thickneſs of the finger, warted from the fallen leaves. Branches few, ſcattered, erect, wand-like, round, ſmooth. Leaves ſcattered but cloſe, patulous, ſeſſile, acute, rolled back at the edge, one-nerved beneath, one-grooved above, ſomewhat rugged, reclining and hanging down. Panicle terminating, erect, looſe, leafy at the baſe. Flowers pedicelled, yellow. Bractes at the top of the peduncle and pedicel, imbricate, ſimilar to the ſcales of the calyx.—Native of the Cape of Good Hope. Shrubby [h].

Introduced in 1774, by Mr. Francis Maſſon. It flowers from june to auguſt [i].

10. Root annual, conſiſting of numerous white fibres. Stem ſingle, upright, about a foot high, branched, leafy, ſlightly angular, ſmoothiſh; but in young plants thinly covered with down towards the top. Leaves alternate, pinnatifid-ſinuate, obtuſe, either altogether ſmooth or elſe looſely woolly beneath: the root-leaves petioled; the ſtem-leaves ſeſſile, and embracing with ears. Flowers terminating, ſcattered or in a ſort of panicle, on ſtriated peduncles, at firſt upright, but pendulous after the flowering is over, and finally upright again; they have often a leaflet or bracte at the baſe. Calyx at firſt cylindrical, but becoming conical, ſmooth: ſcales linear, acute, equal, converging; thoſe at the baſe many but fewer, ſhort, lanceolate, preſſed cloſe; all very conſpicuouſly black at the tip. Florets numerous, yellow, all uniform, hermaphrodite, fertile, length of the calyx. Stigma two-parted, finally ſtanding out. Seeds grooved, pubeſcent, brown. Pappus ſeſſile, rugged, white, almoſt three times as long as the ſeed. Receptacle toruloſe, dotted, ſmooth. This ſpecies, with a few others, having no ray, belongs to the firſt order of the claſs *Syngeneſia*, in the artificial ſyſtem; but naturally it is of this genus.

Native of Europe, Siberia, &c. and no weed is more common in all kinds of cultivated grounds; flowering nearly the whole year.—In the eaſtern counties it is called *Simſon*, or as I have heard it pronounced *Sention* or *Senſhon*, evidently from *Senecio* through the medium of the French *Seneſſon* [k].

The flower-buds and young tops are the food of many ſmall birds, and are given to Canary-birds and others in cages [l]. A ſtrong infuſion of the plant vomits. The bruiſed leaves are a good application to boils [m]. Farriers give the juice to horſes that are troubled with the bottes, whence Mr. Ray conjectures it might be given with advantage to kill worms in the human body. According to Linneus, goats and ſwine eat it. Cows are not fond of it. Horſes and ſheep refuſe it [n].

11. Branches ſtriated. Leaves ſpreading, remote, often quite entire, ſmooth, thickiſh, a little widened at the baſe, embracing, ciliate. Peduncles at the top, few (two to four) one or two-flowered; with a ſetaceous leaflet at the baſe of each. Flowers of the ſame ſize as in the preceding. Calyx untouched, with a few ſmall leaflets at the baſe [o].

12. Stature of *S. vulgaris* or *Jacobæa*. Stem a foot and half high, even. Leaves as in *Siſymbrium amphibium* or *Senecio triflorus*, pinnatifid or ſinuate, toothed, thin. Peduncles many-flowered: pedicels lateral, ſubdivided. Flowers floſcular, as in *S. vulgaris*, yellow, with the calyxes untouched or not mortified. Biennial. Native of Egypt [p]. As is alſo the preceding.

13. Stems herbaceous, a foot and half high, ſtriated. Leaves alternate, remote, linear or filiform, a finger's length: pinnas remote, nine or more. Panicle terminating, faſtigiate with the flowering branches. Flowers yellow.—Found at the Cape of Good Hope by Thunberg [q].

14. Stem fleſhy, weak, grooved, villoſe, two feet high. Leaves petioled, alternate, ſublyrate or gaſh-pinnatifid, looſe, ſmooth, a ſpan long, pale underneath: ſegments oblong, acute, unequally toothed. Stipules two, toothed, over againſt the petiole. Flowers terminating, panicled, floſcular, large. Peduncles bifid or trifid, capillary, drooping, naked. Pedicels ſomewhat ſcaly. Calyx calycled, ſcarcely black at the tips.

Native of Japan, in the iſlands about the port of Nagaſaki; flowering in july, auguſt and ſeptember [r].

15. This is an annual plant. The leaves, according to Willich, vary much; ſometimes they are ovate-lanceolate, the lower with ſmall teeth, the upper with large: in other ſpecimens all the leaves are half-pinnate, with toothed pinnas. The plants which he ſaw, had no rays to the corolla. Among the peduncles there were always ſome three-flowered, but all were not ſo.

Native of Egypt. Introduced in 1776, by Monſ. Thouin. It flowers from july to ſeptember [s].

16. This alſo is an annual plant; native of Egypt. *Erigeron ægyptiacum, mant.* 517. (already deſcribed) is referred to this, in the 14th edit. of *Syſtema Vegetabilium*.

Introduced in 1771, by John Earl of Bute. It flowers in july and auguſt.

17. This is ſhrubby, and native of the Cape of Good Hope; whence it was introduced by Mr. Fr. Maſſon in 1774. It flowers from may to july [t].

18. 19. Theſe are annual plants, natives of Spain.

20. Root annual. Stem a foot high much branched and ſtraggling, not ſimple and erect, as in *S. ſylvaticus*. The whole plant is covered with a fetid clammy liquor ſecreted from the hairs, detaining ſmall inſects, duſt and light ſubſtances. Leaves alternate, ſeſſile, ſcarcely embracing, pinnatifid, eroſe, ſomewhat toothed. Peduncles one-flowered, terminating, ſubſolitary. Flowers in all their parts twice as large as in *ſylvaticus*, but much more ſcattered and leſs numerous, as well as of a brighter gold colour. Calyx hairy, clammy, with a few, linear, looſe, hairy ſcales at the baſe, almoſt as long as the perianth or only half the length. Florets of the diſk numerous, of the ray fewer, five-toothed, immediately rolled back: all are fertile. Pappus appearing ſomewhat rugged when examined with a magnifier [u].

Compared with *S. vulgaris*, the ſtem is taller and ſtronger, the leaves more divided, the flowers larger, and on longer peduncles, the upper ones forming a ſort of looſe corymb, the ſeeds longer and more deeply furrowed, the pappus longer [x]. The hairs on the calyx, and on every other part of the plant at once diſtinguiſh this from *vulgaris*, even though the ligulate florets of the ray ſhould be wanting, as they ſometimes are [y].

Native of Europe, in a calcareous or ſandy ſoil: flowering from july to october. On the fen-banks of the Iſle of Ely, as about Mepole and Chattereſs: alſo on the ſands of Gamlingay. Baldon, Oxfordſhire. About the chalk-pits at Dartford, Kent. And in ſeveral places in Scotland.

21. Root annual. Stem about three feet high, ſtraight, upright, wandlike, leafy, grooved, ſomewhat

Digitized by Google

hairy, corymbed at the top, many-flowered. Leaves numerous, ſcattered, lyrate-pinnatifid, ſomewhat hairy, though almoſt equally unpleaſant in ſcent, leſs viſcid. Flowers numerous, ſmaller by half than in the preceding, and of a paler yellow. Calyx ſlender, ſubpubeſcent, with the ſcales at the baſe ſmall, ſhort and preſſed cloſe. Corollets of the ray ſmall and rolled back: thoſe of the diſk very ſlender and filiform. Pappus appearing rugged when examined with a magnifier. Receptacle ſmall.

Mr. Hudſon was almoſt ſingular in the opinion that this plant is a variety of the *viſcoſus*, from which it is certainly very diſtinct [z]. It has a taller and more firm, though ſlenderer ſtem; the leaves are narrower and more finely divided; the peduncles much more branched, bearing far more numerous flowers, the terminating ones forming a large broad-topped ſpike. The flowering heads are much ſmaller, the ſeeds ſhorter and broader, and the pappus ſhorter. The leaves, when in an hot and ſunny ſituation, are frequently clammy, but not ſo much as in *viſcoſus* [a].

Dr. Stokes remarks, that the ſtem has a fine woolline ſs on it, of ſhort tapering zigzag hairs; that the upper branches riſe nearly to the ſame height with the ſtem; that the leaves are ſomewhat woolly, with ſcattered ſhort hairs, tapering but not tipped with glands; that the peduncles are ſomewhat cottony; that the calyx is conical and ſomewhat woolly, with the ſcales at the baſe awl-ſhaped, few, dead at the ends, thrice as ſmall as thoſe of the cup; and that the corollets are of a full yellow. Dr. Withering obſerves, that the edges of the leaves are rolled back, the ſcales of the calycle few, ſhort, ſlender, ſcarce ſenſibly dead at the ends, and the florets of the ray rolled back cloſe up to the cup.

Native of Europe, in a gravelly or ſandy ſoil, in buſhy ſpots upon heaths and commons, where trees or furze have been cut down, eſpecially where fern or other plants have been burnt in the preceding autumn. It flowers in july [b].

22. This is an annual plant, of the ſame ſtature with the common ſort; but the leaves are larger, blunter, repand-ſinuate, and quite entire. The ſtem is leſs divided and very hirſute. The peduncles ſolitary and viſcid. The flowers ſolitary, the ſame ſize with thoſe of *S. Jacobæa*, with the ray leſs revolute. The calyx is not mortified at the tips.—Native of Sicily, Spain and the Pyrenees [c].

23. This alſo is an annual plant, pubeſcent and glaucous or aſh-coloured.—Native of Egypt [d].

24. Root annual. Stem a hand high, erect, roundiſh, thinly haired, purpliſh, ſhining, very ſimply branched. Branches alternate, ſhort, ſpreading, three or four. Leaves alternate, ovate or oblong, bluntiſh, having few, remote, ſtout ſerratures, thickiſh, above duſky green, varicoſe and hairy, beneath blood-red: petioles ſhorter by half than the leaves, half-embracing, very ſmooth, ſhining, channelled, ciliate. Peduncles terminating, ſolitary, one or two-flowered, almoſt the length of the ſtem, filiform, erect, thinly haired, purpliſh. Calyx cylindrical, equal, with five acute remote ſhort ſcales to the calycle. Ray of the corolla compoſed of from ſixteen to twenty revolute florets, three-lobed at the tip, violet-coloured underneath. Florets in the diſk pale purple. Seeds ovate, ſmooth. Pappus quite ſimple, white.

Native of Egypt; whence the ſeeds were ſent to Sweden by Roque in 1761 [e].

25. Roots numerous, capillary, twiſted, in bundles, annual. Stems ſeveral, decumbent at the baſe, ſubvilloſe, ſimple or little branched. Leaves decurrent, ſmooth or ſcarcely villoſe, unequally toothed, ſometimes laciniate. Flowers few in terminating corymbs, on ſhort peduncles. Calyx cylindrical, calycled, with the interior leaflets linear, almoſt equal, ſharpiſh. Corollets yellow. Seed ſmall, oblong. Pappus ſeſſile, villoſe, whitiſh. Receptacle naked.—Native of all Barbary; flowering in winter.

26. This alſo is annual. Stem ſtriated, ſmooth, ſimple, or little branched. Lower leaves decurrent, elliptic; upper ſeſſile, embracing. Calyx cylindrical, calycled; with the inner leaflets awl-ſhaped, not dead at the end. Corolla the ſame ſize as in *S. Jacobæa*, yellow. Seed ſmall. Pappus villoſe, ſimple, whitiſh. Receptacle naked.—Native of Barbary, near La Calle [f].

27. This has an herbaceous perennial ſtalk, branching out at the bottom, and riſing about two feet and a half high; having narrow leaves at bottom, ſeven or eight inches long. The upper leaves are ſmaller, and embracing; they are very clammy. The upper part of the ſtalk divides into ſeveral very long peduncles, each ſuſtaining one yellow flower.

[Native of the Cape of Good Hope. Cultivated in 1732, by James Sherard, M. D. It flowers moſt part of the ſummer [g].

28. Root perennial. Root-leaves ſmooth, blunt, crenate, with the petioles woolly at the baſe. Stems a foot high, having three or four ſmall leaves on them, which are half embracing and pinnatifid. There is one terminating flower, and frequently lateral ones that are ſeſſile: they are yellow with a violet-coloured ray. Native of the Cape of Good Hope [h].

29. The rib of the leaves, eſpecially the lower ones, is often ſet with ſoft prickles.—Native of the Cape of Good Hope, where it was found by Maſſon, and introduced in 1774. It is biennial, and flowers from july to ſeptember [i].——This, like the preceding and next ſpecies, has a yellow diſk with a purple ray.]

30. This is an annual plant, having many herbaceous branching ſtalks, near three feet high. The flowers are produced in bunches on the top of the ſtalks; they are large, the ray of a beautiful purple colour, and the diſk yellow.

Native of the Cape of Good Hope. Flowering from june or july till autumn froſts come on. [Cultivated in 1700, by Charles Dubois, Eſq. [k]

Since his time a variety with very double purple, and another with white flowers, equally double, have been introduced, and the former of theſe is now chiefly cultivated, in preference to the ſingle.

One year a hybrid or mule plant appeared plentifully in the botanic garden at Cambridge, evidently generated from a mixture of this *S. elegans* with the *vulgaris* or common Groundſel; it had entirely the herb of the latter, with a ſmall ray of a pale purple colour. Being annual and barren it diſappeared at the end of the ſeaſon.

31. Root annual. Stem various in luxuriance, erect, branched, often a little hairy. Leaves ſeſſile or embracing the ſtems with little ears, deeply pinnatifid; the ſegments narrow, almoſt linear, acute, remote, toothletted, flat, nearly ſmooth, even, often purpliſh beneath. Corymb terminating, looſe, few-flowered, bracteate. Flowers of a bright golden yellow. Calyx almoſt hemiſpherical, ſmooth, with a few looſe ſmall ſcales at the baſe. Florets of the diſk very numerous:—of the ray many, ſpreading, elliptic, broad, quite entire at the top, finally revolute. Seeds tomentoſe. Pappus rugged.

The whole habit, and a peculiar ſmell ſomewhat like Tanſy or Mugwort, diſtinguiſh this plant ſufficiently. It flowers from june to the very end of autumn.

Native of the South of France according to Linneus, who received it from Dillenius, under the name of *Jacobæa laciniatis foliis, tanaceti odore*. Probably Dillenius collected theſe ſeeds from the walls about Oxford, where it grows abundantly. Though long ſince noticed there by Sir Joſeph Banks, it did not find its way into the *Flora Oxonienſis*, or any other, till Dr. Smith inſerted it in his *Flora Britannica*. It is certainly the *ſqualidus* of Linneus. (Krocker has it in his *Flora Silefiaca*.) But whether it be the *S. gallicus* of Villars (3. 230.) we have not materials to determine [l].

32. Stem upright, three or four feet high, hardiſh, tomentoſe. Leaves hard, hoary, ſubhirſute, divided into narrower linear pinnas, with ſharper points, having parallel lines all over them. The ſcales of the

[z] Smith. [a] Woodw. Mſs. [b] Engl. bot. [c] Linn. ſpec. [d] Idem. [e] Linn. dec. [f] Desfontaines. [g] Hort. kew. [h] Linn. amoen. [i] Hort. kew. [k] Idem from Plukenet. [l] Smith.

Digitized by Google

calyx end in a reddiſh point, but by no means a black one. The ſcales of the calycle are preſſed cloſe and are hirſute at the baſe. The flower is of a paler yellow than in *S. Jacobæa*[m]; from which Haller does not diſtinguiſh it. Pollich keeps it ſeparate, with Linneus and others; but ſeems inclined to think Haller in the right.

Willich remarks, that it puts off all pubeſcence, when tranſplanted into a garden; but that the other differences between this and *S. Jacobæa* continue.

Native of Sweden, Germany and Sileſia; not of Britain.

It nearly reſembles *S. ſylvaticus*, of which perhaps it may be a variety[n].

33. Root perennial, moderately creeping. Stem ſtraight, grooved, leafy, woolly, one to three feet high, corymbed at the top. Leaves numerous, alternate, embracing, toothed here and there, more or leſs woolly, eſpecially on the lower ſurface, which is often white. Flowers of a golden yellow colour, in a terminating bracted corymb. Calyx-ſcales broad, more or leſs woolly, with a white membranous border, a little browniſh at the tip, though leſs ſo than in ſome other ſpecies: calycle ſmall, looſe. Florets of the ray linear-oblong, obtuſe, three-toothed, ſpreading but ſoon revolute. Seeds hairy; with a rugged down or pappus.

No plant is more variable in the appearance of its foliage. On a calcareous ſoil the leaves are very much rolled back, and quite white beneath with a thick cottony web, of which the ſtem always more or leſs partakes: in damp ſhady places they are almoſt flat, and green, though always paler, and ſomewhat ſhaggy on the under ſide. Such are the extremes of the two varieties marked by Dr. Withering; but intermediate ſpecimens are always to be found[o].

Native of Auſtria and England. About London, near woods, under hedges, and among buſhes: as about the Oak of Honour wood near Peckham. Holm, Norfolk. Bath hills, near Bungay, Suffolk. Baydales, Darlington, &c. It flowers in auguſt.

The ſynonyms given by Linneus to the preceding ſpecies, probably belong to this, except that from the *Iter ſcanicum.*]

34. This is a perennial plant of low growth, the ſtalks ſeldom riſing a foot high. The whole is covered with a very white hoary down. The leaves are winged and indented. The flowers are collected into a cloſe round corymb on the top of the ſtalk, and are of a gold colour.

[Stems a finger's length, leafy. Leaves like thoſe of *Achillea clavennæ* or *Othonna maritima*, but ſmall, pinnatifid, obtuſe, white and marked with lines[p].

Native of the Alps, Auſtria and Carniola, Sileſia, the South of France, and the Pyrenees. Cultivated in 1759 by Mr. Miller. It flowers in july and auguſt[q].]

35. Root perennial, compoſed of many long ſlender fibres, which ſtrike deep into the ground, and ſpread on every ſide. Stems two feet high, becoming a little woody in autumn, leafy their whole length. Leaves reſembling thoſe of Hog's-fennel. Flowers in bunches on the top of the ſtalks, yellow.

[The root-leaves are bipinnatifid: the ſtem-leaves ſimply pinnatifid. Peduncles pubeſcent, three or four, commonly two-flowered[r].

Native of the mountains of Stiria and Carinthia, Switzerland, the South of France and Piedmont.—Cultivated in 1759, by Mr. Miller. It flowers from july to october[s].

36. Stem erect, even. Leaves ſmooth, bipinnate except the upper ones, which are ſimply pinnate. Corymb terminating, compound, faſtigiate, yellow. Calyxes rufeſcent.—Native of Canada[t].

37. Native of the Cape of Good Hope, where it was found by Thunberg[u].

38. Stems purpliſh, branched, erect. Leaves pinnatifid, tomentoſe underneath. Flowers racemed, panicled, erect. Calyx cylindrical, tomentoſe. Receptacle conical, naked.—Native of Algiers. Perennial.

39. Stem herbaceous, erect, villoſe, ſubhirſute, ſtriated, ſimple or little branched. Leaves ſubhirſute, two-eared at the baſe. Peduncles many-flowered. Flowers cluſtered, corymbed, on ſhort pedicels, the ſame ſize as in the firſt ſpecies. Calyx cylindrical, ſimple; the leaflets awl-ſhaped, not dead at the end. Corollets of the ray yellow, fine as hairs, the length of the calyx. Seed ſlender, ſmooth. Pappus ſimple, ſnow-white, villoſe, ſeſſile, longer than the calyx. Receptacle naked.—Native of the deſert, Barbary. Annual[x].

40. Stem erect, ſmooth, ſtriated, branched, often the thickneſs of a finger. Leaves petioled, ſubtomentoſe but ſometimes ſmooth. Lower ſtem-leaves pinnate-lobed, with the lobes ovate or ovate-oblong, blunt: the upper ones ovate-oblong or lanceolate. Flowers of the ſame ſize with thoſe of *S. Jacobæa*, upon pedicels which have needle-ſhaped leaflets on them. Calyx cylindrical: leaflets linear-lanceolate, equal, ſubacute. Florets of the ray yellow, ſmall, linear. Seed very ſmall, ſmooth, crowned with a ſimple villoſe pappus. Receptacle naked, convex. Perennial.—Native of Africa, near Belide in Algiers.

41. Roots capillary, ſubvilloſe. Stem erect, ſtriated, ſmooth. Peduncles erect, ſlender, leafy, one-flowered. Leaves ſubhirſute, awl-ſhaped, from the middle to the top pinnate: pinnules rather remote, linear-ſubulate, unequal; ſometimes contorted, entire, and ſometimes tooth-pinnate. Flowers few, corymbed, the ſame ſize as in *S. Jacobæa*. Calyx ſimple, cylindrical, ſmooth: leaflets linear, equal, untouched or not dead at the tip. Corollets of the ray yellow, linear. Seed very ſmall, oblong. Pappus ſimple, villoſe, white, ſeſſile. Receptacle convex, naked. Annual; flowering in winter.—Native of Barbary, in wet ſands of the deſert[*].

42. Root perennial, fibrous creeping, truncated. Stem two, three or four feet high, ſtreaked, upright, branched, generally ſmooth, often tinged with purple, leafy, corymbed, many-flowered. Leaves commonly dark-green without any down; but ſometimes both theſe and the ſtem are tomentoſe or cottony: thoſe next the root pinnatifid at the baſe only, with a large oval ſinuated ſegment at the extremity; on the ſtem they are pinnatifid throughout, and their ſegments laciniated, the laciniæ being more numerous and finer in proportion to the dryneſs of the ſoil. Corymbs terminating, many-flowered, bracted, ſmooth. Flowers deep yellow or gold-coloured. Calyx ſmooth, grooved, cylindrical, ſhort; having few, looſe, awl-ſhaped ſcales at the baſe. Florets of the ray linear-oblong, three-toothed, finally revolute, twelve or thirteen: in the diſk about ſixty. Seeds hairy. Pappus rugged[y].

Dr. Stokes remarks, that the filaments towards the end thicken into flat ovate glands, diſappearing as ſoon as, or ſoon after the pollen is ſhed, rendering it probable that they are intended for the nouriſhment of the pollen.

Ragwort is very common on the ſand-hills of Holland, without any ray to the corolla. Sherard obſerved it thus on the ſea-ſhore, three or four miles from Drogheda. Perhaps this is the effect of the ſea air, which is well known to be deſtructive to the more tender parts of vegetables. In Marazion marſh, Cornwall, it has been found with rayleſs flowers, and the whole plant hoary with a denſe cottony ſubſtance[z]. I have remarked the winter plants of the common Groundſel to be covered with a thick coat of cotton.

Ragwort is found in moſt parts of Europe, in England it is a common weed in graſs grounds. It is called not only Ragwort or Ragweed, but St. James's wort, Canker-wort; and in the north Seggrum, Seggram or Seagrim.

If this plant be gathered before the flowers open, and uſed freſh, it dyes wool of a full green, but the colour is apt to fade. If woollen cloth be boiled in

[m] Pollich [n] Engl. bot. [o] Smith. [p] Linn. ſpec. [q] Hort. kew. [r] Linn. ſyſt. [s] Hort. kew. [t] Linn. ſpec. [u] Linn. ſuppl. [x] Desfontaines. [*] Idem. [y] Smith, Fl. ruſt. [z] Withering.

alum

alum water, and then in a decoction of the flowers, it takes a beautiful deep yellow. It is said that kine and horses will eat it when young [a]; but much of it escapes their bite, flowers and seeds, and fills the pastures with a large rank weed.

43. Root perennial. The herb commonly quite smooth, but in dry places sometimes a little woolly. Stem erect, branched, leafy, frequently purplish at the base like the preceding: it is also corymbed, but with larger and much fewer flowers. Leaves bright not dark green: the lower petioled, obovate or elliptic, undivided, and commonly quite entire; the upper ones sessile or embracing, lyrate-pinnatifid, serrate, quite entire at the end. Flowers gold-flowered, handsome. Calyx short and almost hemispherical, smooth, scarcely calycled. Florets of the ray spreading, elliptic, three or four-toothed, of various breadths, finally revolute. Seeds quite smooth, in which it undoubtedly differs from the preceding. Pappus rugged [b].

Dr. Stokes remarks, that the stem and leaves are quite smooth, the root-leaves with the terminating leaflet oblong; the calyx-scales fifteen to twenty-one, dead as it were and brown at the points, florets of the ray about twenty-one, and the florets thickening towards the end into oblong glands, as in common Ragwort.

Mr. Woodward has observed that it is sometimes found without any ray to the flowers.

Native of Denmark and England, in marshes, ditches, wet meadows and watery places in general: flowering in july and august.]

44. Root perennial. Root-leaves many roundish, about an inch and half over each way, of a purplish colour on their under side, and crenate on their edges. Stems near two feet high, with a few lyrate leaves on them: the upper part divides into several long slender peduncles, each sustaining one erect flower, which is yellow, and has few florets in the ray.

[Native of Virginia and Canada. Cultivated in 1759 by Mr. Miller: it flowers in may and june [c].] Mr. Miller says june and july; and that the seeds ripen in autumn.

[Linneus seems to think that it is scarcely distinct from *S. Jacobæa*.

45. This is one of the tallest growing species. The leaves are deeply sinuate, almost pinnate, with the lobes rounded, and muricate at the edge.—Found at the Cape of Good Hope by Thunberg [d].

46. Stem erect, branched at bottom: branches grooved, smooth. Leaves remote, smooth, even, acute, unequally toothed, an inch and half long; the last segment very large, cordate-lanceolate; side-ones one or two on each side, oblong, a little narrower at the base, remotely toothed. Petioles much shorter than the leaves, with a rounded toothed earlet at the base on each side. Corymb terminating; with an awl-shaped scale at the base of each peduncle, and two or three smaller on the pedicels. Peduncles smooth, mostly three-flowered, except the last which are one-flowered. Calyxes simple, untouched or not black at the point. Ray of the corolla eight or ten-flowered. It is distinguished from *alpinus* by its naked lanceolate leaves, and its simple untouched calyxes [e].

47. Stem herbaceous, striated-angular or round, erect, simple, two feet high or more, branching at top into a corymbed panicle. Leaves alternate, remote, bluntish, beneath hoary and veined. Petioles the length of the leaves, having two or four leafy teeth in the middle, as in *Erysimum Barbarea*. One corymb terminating, and several axillary solitary, on longer peduncles. Pedicels with small awl-shaped scales scattered over them. Calyx calycled, equal, mortified at the points. Calycle small, pressed close. Corolla yellow, like that of *S. Jacobæa*. Transplanted into good ground in a garden, it has a very branching stem with laciniate leaves, and appears like a different plant.

Native of the mountains of Switzerland, Sweden and Germany [f].

48. Stem two feet high, simple except at top, where it is branched. Leaves linear, subpinnate; the pinnas remote, linear, long. Flowers in umbels, with awl-shaped leaflets scattered over the pedicels. Calyxes even. Ray of the corolla purple. In the *Amoenitates* it is said to be yellow with red streaks beneath.—Native of the Cape of Good Hope [g].

49. Found at the Cape by Masson, and introduced in 1774. It flowers from july to october [h].

50. The peduncles have small acute scales scattered over them. It has the calyx of a *Senecio*, although the scales are not mortified at the point [i].—Native of Spain, Italy and Russia.

51. This is a smooth plant, found at the Cape of Good Hope by Thunberg [k].

52. Root of many long simple fibres, perennial, somewhat creeping. Stem from three to six feet or more in height, perfectly straight, upright and simple, leafy, round, hollow, striated, loosely clothed with deciduous cottony down, which likewise invests the young leaves and flower-stalks. Leaves scattered, numerous, sessile, lanceolate, acute, acutely serrate, narrow and entire at the base, smooth above, paler and generally downy beneath. Corymb terminating, few-flowered, the lower peduncles axillary. Bractes awl-shaped. Flowers above an inch in diameter, bright yellow. Calyx smoothish, with the scales at the base linear. Florets of the ray linear, five-toothed, spreading but little recurved. Seeds hairy. Pappus minutely rugged. Receptacle set with short hairs between the seeds, as is often the case in many plants in which that part is said to be naked, for these hairs are very different from the long chaffy scales to be found in some genera [l].

Native of some parts of Europe, in fens and marsh ditches; flowering from june to august. It was not known to be indigenous of Britain in the time of Gerarde, Parkinson and Johnson. Ray found it in marsh ditches and banks in the Isle of Ely, but rarely. Near Stretham-ferry, where he particularly remarked it, no one has found it lately. Mr. Relhan marks it at Littleport, Chatteress, and in Bardwell fens. Mr. Hemsted found it in Lakenheath fen near Wangford, Suffolk. And the Rev. H. J. Wollaston, on the banks of ditches near a piece of water called Braford, about half a mile from Lincoln. Ray also remarked it in his travels abroad near Nantua, in going from Geneva to Lyons.

53. Root perennial, fibrous, not creeping. Stem single or few, from a foot and half to three feet and half, erect, round, often very slightly angular, or sometimes grooved towards the top, the whole pale green or purplish here and there, smooth and shining or hairy, thickness of a little finger or goose quill, leafy up to the very peduncles. Leaves irregularly alternate, the upper ones gradually less and less, so as not to exceed the flowers in height, hence the uppermost are very small. They are acuminate, sessile, from three to six inches long, according to the size of the stem; the upper surface is smooth, the lower in some plants hirsute or villose, in others shining: serratures unequal, in some double but in the greater part not so. Branches fewer or more spring at an acute angle from the axils of the upper leaves, and collect the flowers into a compound corymb. Peduncles variously branched so as form a sort of umbel. Calyx-scales about ten, and commonly five in the calycle. Corollets in the ray five, very seldom four, in the wild plant, but more when cultivated, spreading very much, yellow, oval-oblong, emarginate: in the disk twelve or more [m].

Native of Germany, Austria, Switzerland, Piedmont and Siberia. Introduced in 1775, by Drs. Pitcairn and Fothergill. It flowers in july [n].

54. Root perennial, creeping, straight, from two or three to five feet in height, angular, leafy, smooth, corymbed at top. Leaves alternate, sessile, acute, smooth or minutely pubescent; the upper ones gra-

[a] Withering. [b] Smith. [c] Hort. kew. [d] Linn. suppl. [e] Vahl. [f] Linn. suec. [g] Linn. mant. & amoen. [h] Hort. kew. [i] Linn. spec. [k] Linn. suppl. [l] Smith. [m] Jacqu. obs. [n] Hort. kew.

Digitized by Google

dually leſs. Corymb many-flowered. Bractes linear-lanceolate, acuminate. Pedicels angular, pubeſcent. Flowers yellow. Calyx ſomewhat woolly, with the ſcales at the baſe lanceolate. Florets of the ray elliptic, long-clawed, ſcarcely toothed at the end. Seeds ſmooth. Pappus minutely rugged [o].

It is eaſily diſtinguiſhed, ſays Linneus by its appearance, ſize, wide leaves, and very creeping root.

Native of many parts of Europe. Found in Britain between Wells and Glaſtonbury, by Bobart; near Halifax, by Newton; at Salkeld in Cumberland, by Nicholſon; about Clapham and Ingleton, by Hudſon; near Longtown and on the ſide of the river below Carliſle, by Mr. Jackſon; near Preſton hall, between Kirkby Lonſdale and Kendal in Weſtmoreland, in 1782, alſo in the King's Park, Edinburgh, by Dr. Smith; but in the laſt-mentioned place, probably planted.]

55. Root perennial. Stem annual. Lower leaves a foot long, four inches broad in the middle, and ſomewhat ſhaped like a ſcymitar, the midrib being curved outwards towards the point; they are ſmooth, and ſlightly indented on their edges. Stem four feet high, with leaves growing ſmaller the whole length, and embracing it half round. Flowers terminating in a compact corymb, of a deep yellow colour.

[Stem the height of a man or even more, the thickneſs of a finger at bottom, ſtreaked and a little hairy, towards the top ſmooth and ſomewhat angular. Root-leaves ſpreading in a ring, long, wide and thick, ſhaped like thoſe of *Lepidium*, moderately and irregularly toothed, ſmooth above, paler and ſomewhat hoary beneath, with oblique ſlender veins from a whitiſh midrib. Leaves on the ſtem alternate, narrower, deeply toothed, thick like the others, ſmooth beneath, with veins ſo ſlender as to be ſcarcely viſible. Bractes at the origin of the peduncles and pedicels. Flowers yellow. Calyx ſtriated, calycled. Florets in the ray from two to five, notched at the end [p].]

Diſcovered by Tournefort in the Levant, and the ſeeds ſent by him to the royal garden at Paris. It was cultivated in 1732 by James Sherard, M. D. and flowers in july and auguſt [q].

56. Root perennial. Stem erect, two feet high, even. Leaves ſeſſile, few, quite entire, with a whitiſh rib. Flowers in a ſort of corymb, yellow, with about fifteen florets in the diſk. Calyx mortified at the edge. Calycle compoſed of three or four ſcales.—Native of Siberia [r].

57. Leaves ſmooth on both ſides. Bractes ſetaceous under the calyx. The upper ſtem-leaves become ſmall, ſo that the corymb appears as if it were on a very long peduncle; whereas in the *ſaracenicus* biggiſh leaves continue to the very corymb. It reſembles *Cacalia ſaracenica* [s].

Native of the Levant, Germany, Auſtria, the South of France, and Piedmont. Cultivated in 1570 by Mr. Hugh Morgan, according to Lobel. It flowers from july to ſeptember [t].

58. Stem quite ſimple, villoſe. Root-leaves ovate-oblong, petioled, ſerrate, bluntiſh, thickiſh, villoſe beneath, glaucous above. Stem-leaves ſmall, lanceolate, and almoſt awl-ſhaped. Flower terminating, often ſingle, thickiſh. Calyx calycled.—Jacquin diſcerned the progreſſive varieties; but Haller will not allow that they all agree [u].

Villars obſerves, that the fat thick leaves with unequal teeth are more or leſs ſmooth, they vary alſo in figure and ſize; but their down preſſed cloſe and unequal, like a ſpider's web, is never wanting when the plant is young; and their teeth a little bent down is a conſtant mark. The calyx is ſcaly and villoſe, the lower ſcales a little ſtraddling, and they are all mortified at the end. The flower is large, deep yellow, and compoſed of more florets than in any other ſpecies. This plant partakes of *Senecio*, *Cineraria*, *Doronicum*, and *Solidago*. It agrees with the firſt of theſe in the calyx; but in habit and other characters it differs from it.—Native of the South of Europe. Cultivated in 1705 by Dr. Uvedale, according to Plukenet. Flowers from july to ſeptember [x].

59. Leaves linear, ſcattered, long, naked, rugged. Flowers corymbed. Linneus doubts whether *S. grandiflorus* of Bergius, belongs to this ſpecies; the leaves being more toothed, and the flowers twice as big.—Native of the Cape of Good Hope [y].

Introduced in 1775 by Monſ. Thouin. It flowers from auguſt to november [z].

60. This is ſingular for its rigid mucronate leaves, half-toothed on each ſide towards the point.—Found at the Cape by Thunberg.

61. This is a little ſhrub, a foot and half high, determinately branched, roundiſh, even. Leaves ſcattered, reſembling thoſe of Juniper, but a little wider, half-embracing, an inch long, rolled back at the ſides, even, mucronate. Peduncles terminating, elongated, with four or five flowers at the top on ſtraddling pedicels. Flowers yellow, with the ray ſpreading.—Native of the Cape [a].

62. Plant biennial. Stature of *S. rigidus*, but much narrower in all its parts. Stem four feet high, round, ſtriated, green, having white hairs ſcattered over it. Branches on the lower part of the ſtem ſpreading very much. Leaves lanceolate, ſeſſile, embracing, revolute, ſerrate with ſharp teeth, having obtuſe ſinuſes; above green, ſhining, ſomewhat rugged, beneath veined, ſubvilloſe, green. Rudiments of the branches from each axil of the leaves. Scapes terminating, round, much narrower than the ſtem, filiform, very long, ſmoother, ſtriated, having linear undivided leaves ſcattered over them below, not toothed but ſerrate-ſpiny and almoſt naked. Corymbs terminating, alternate, ſubdivided. Calyxes mortified at the points. Corollas yellow, with eight ovate florets in the ray ſcarcely three-toothed. It has the appearance of *Serratula arvenſis*.

Native of Conſtantinople [b].

63. The whole plant very ſmooth. Leaves thickiſh, veinleſs, often having minute, few, remote teeth about the edge. Petiole ſhorter than the leaf. Corymbs terminating. Bractes two or three linear, at the baſe of the peduncles; ſmaller on the pedicels. Calyx cylindrical, brown, paler when riper: calycle eight-toothed; the teeth very ſmall, and a few ſcalelets beſides at the baſe of the calyx. Ray of the corolla five-flowered [c].]

64. Stem ſeven or eight feet high, ſending out branches on every ſide the whole length. Leaves about two inches and a half long, and almoſt two broad, hoary. Flowers in looſe bunches at the extremity of the branches, almoſt in form of an umbel, of a pale yellow colour.

[Florets in the ray ſometimes only four or five, ſometimes ſix or ſeven and even more, ſhort and entire. Seeds ſmall, ſlender [d].

Native of the Cape of Good Hope. Cultivated in 1732, by James Sherard, M. D. It flowers in july [e].]

65. This has a very branching ſhrubby ſtalk, four or five feet high, ſending out branches irregularly on every ſide. Leaves ſtiff, irregular, about three inches long, and three quarters of an inch broad, deeply cut on their edges, and of a gray colour on their under ſide. The flowers grow in looſe bunches at the end of the branches, and are of a pale yellow colour.

[Native of the Cape of Good Hope. Cultivated in 1731, by Mr. Miller. It flowers in june and july.

66. This alſo is a native of the Cape, where it was found by Maſſon, and introduced in 1774. It flowers in july and auguſt, and is ſhrubby [f].]

67. This riſes with a ſhrubby branching ſtalk ſix or ſeven feet high. It is cloſely ſet with rugged embracing leaves; thoſe on the lower part four inches long, and an inch and half broad at the baſe, gradually diminiſhing in ſize to the top; they are ſtiff, hairy, dark green, oblong, heart-ſhaped, indented.

Digitized by Google

The flowers are produced at the end of the branches, and are of a bright yellow colour.

[Stem rigid, rugged, inelegant. Leaves rigid, appearing as if oiled on the upper ſurface, but not ſmooth; beneath they are hoary and ſomewhat villoſe. Flowers ſmall, with five yellow florets in the ray, which are remote and entire [g].

Native of the Cape of Good Hope. Cultivated in 1759 by Mr. Miller. It flowers from june to ſeptember [h].

68. The plant is clothed all over with white wool. Leaves roundiſh-ovate, quite entire or having at moſt one or two apparent toothlets, woolly but finally becoming naked, on long petioles embracing the ſtem with their widened baſe.—Native of the Cape of Good Hope [i].

69. This is one of the loftier ſpecies. Leaves ſomewhat fleſhy, glaucous.

70. The whole is generally fleſhy. It varies with lanceolate leaves.

71. Root-leaves elongated, ſinuate, and with the lobes ſerrate, towards the root involved in cotton. Stem almoſt leafleſs, or leaves very few, partially embracing.

72. 73. Theſe, with the three preceding, are natives of the Cape of Good Hope, and were found there by Chevalier Thunberg.

74. Stems almoſt proſtrate, a foot long, the ſize of a coarſe thread, ſomewhat branched at the baſe. Leaves alternate, petioled, bluntiſh, even on both ſides. Peduncle terminating, elongated, few-flowered. Calyx ſimple, not calycled. Corolla yellow. Ray with a bifid fertile ſtigma.—Found at the Cape by Sparrmann.

75. Stems erect, two feet high, ſtriated, herbaceous. Leaves alternate, diſtant, more dilated at the baſe, obſcurely decurrent. Panicle terminating. Ray of the flower ſpreading, purple.—Found at the Cape by Thunberg [k].]

PROPAGATION AND CULTURE.

1. Sow the ſeeds upon a hotbed in the ſpring, and when the plants are fit to remove, tranſplant them to another hotbed to bring them forward, and afterwards plant them in a warm border, where they will flower in july, and their ſeeds will ripen in autumn.

8. Part the roots in the ſpring. Plant the offſets in pots filled with light kitchen-garden earth, and plunge them in the tanbed in the ſtove, where they muſt remain.

27. Cut off the ſide ſhoots in any of the ſummer months, and plant them in a ſhady border, where in five or ſix weeks they will take root, and may then be taken up and planted in pots, placing them in the ſhade till they are well rooted: then remove them to an open ſituation, obſerving to water them duly in dry weather. In winter place them under a frame, [or in the dry ſtove. This management applies to the numerous ſpecies from the Cape of Good Hope.]

30. If the ſeeds, which ripen in autumn, be permitted to ſcatter, plenty of plants will riſe the ſpring following. Or if ſown upon a bed of common earth in the ſpring, the plants may be tranſplanted into the borders of the flower-garden. If ſome of the plants be put into pots, and houſed in winter, they may be preſerved till ſpring. [The varieties with double flowers are continued by cuttings.]

34. Slip off the heads in the ſpring, and plant them in a bed of loamy earth in a ſhady ſituation: when they have put out roots, tranſplant them into an eaſt border, for they prefer a ſituation not too much expoſed to the ſun. Having fine hoary leaves, this ſpecies makes a pretty diverſity, when intermixed with other plants. Requiring little culture and not taking up much room, it deſerves a place in ſmall gardens.

35. Sow the ſeeds upon a bed of loamy earth, expoſed only to the morning ſun. When the plants are fit to remove, tranſplant them to a ſhady border, where they may remain till autumn, obſerving to keep them clear from weeds all the ſummer: then tranſplant them to the places where they are to remain. The following ſummer the plants will flower and produce ſeeds; and the roots will continue, if they are in a ſhady ſituation and a loamy ſoil.

[42. This rank weed, ſo troubleſome in dry graſs grounds, may be deſtroyed gradually by conſtant mowing; moſt effectually by pulling it up by hand after rain. Feeding the land with ſheep is ſaid to be an infallible cure for it; and it is affirmed that they eat it with ſo much greedineſs as very ſoon to deſtroy it [l]. This muſt be whilſt it is yet very young.]

44. Plant the offſets in autumn in an eaſt border of loamy earth, allowing each plant two feet room to ſpread.

52, 53, 54, 55. Theſe are eaſily propagated by ſeeds or parting their roots: the latter mode is generally practiſed when the plants are once obtained, that being the moſt expeditious method, eſpecially for the 54th ſort, the roots of which ſpread and increaſe too faſt where they are not confined. The time for dividing and tranſplanting theſe roots is in autumn, when the ſtalks decay. Theſe plants are too large for ſmall gardens, but are proper for large borders in extenſive gardens, or for the ſides of woods and plantations, where they may be allowed room; and in ſuch places, intermixed with other tall-growing plants, they will add to the variety.

64, 65, 66, 67. Theſe are too tender to live in the open air through the winter in England, but are ſo hardy as to only require protection from hard froſts; ſo if they are kept in pots and placed either under a frame in winter, or in a common green-houſe with other hardy kinds of plants, which require a large ſhare of air in mild weather, and only require to be ſcreened from hard froſt, they may be preſerved in England. They are all eaſily propagated by ſeeds or cuttings, but the latter being the moſt expeditious method is generally practiſed here. If the cuttings are planted in a ſhady border during any of the ſummer months, they will readily take root, and then they ſhould be taken up with balls of earth to their roots, and each planted in a ſeparate pot filled with good kitchen-garden earth, and placed in the ſhade till they have taken new root; then they may be removed to a more open ſituation, where they may remain till there is danger of ſharp froſt, when they ſhould be removed into ſhelter, and treated in the ſame way as other hardy kinds of green-houſe plants.

If theſe plants are propagated by ſeeds, they ſhould be ſown on a bed of freſh earth, expoſed only to the morning ſun the beginning of april, obſerving in dry weather to moiſten the ground now and then, which will forward the vegetation of the ſeeds. When the plants come up, they muſt be kept clean from weeds till they are fit to remove, when they ſhould be planted in pots, and treated in the ſame way as thoſe raiſed from cuttings.

DESCRIPTION, *&c.*

Leaves radical four, blunt, naked, crenate; the two lower oppoſite, larger, ſubpetioled, roundiſh; the two upper oppoſite, oval, ſeſſile, narrower. Scape filiform, naked, terminated by a ſimple umbel, compoſed of ſeven or eight filiform, one-flowered, naked peduncles; with a very ſmall involucret. In the natural orders it approaches to *Saxifraga* and *Sedum*.

Native of the Cape of Good Hope [m]. Introduced in 1774, by Mr. Francis Maſſon. It flowers in auguſt and ſeptember, and is perennial [n].

Loureiro has given the name of *Septas repens*, to a plant of the claſs *Didynamia* and the order *Angioſpermia*, allied to *Thunbergia*.

SEPTFOIL. See *Tormentilla*.]

Lin. ſyſt. 816. *Thunb. jap.* 28.

Leaves enſiform convoluted ſickle-form, flowers erect.

14. Serapias regularis.
Forſt. prodr. n. 312.
Thelymitra longifolia. *Forſt. gen.* 49.

Bulbs ovate fibrous, leaves ſheathing enſiform keeled, ſcape erect ſpiked, corollas ſix-petalled.

DESCRIPTIONS, *&c.*

1. Root perennial, creeping horizontally, throwing out many long fibres, fleſhy but by no means bulbous, thriving in the moiſt black vegetable mould of damp woods. Stem ſimple, erect, near two feet high, clothed with ſeveral alternate, ovate or lanceolate leaves, the lower ones ſheathing, the upper ſeſſile, all ſtrongly nerved, thin, rather rigid, not fleſhy. Spike erect, many-flowered. Bractes lanceolate, the lower ones longeſt. Flowers more or leſs drooping, on ſhort peduncles, of a browniſh green colour, but ſometimes dark purple (which is Mr. Hudſon's variety β;) petals ovate, pointed, concave. Nectary ſhorter than the petals, concave, with a projecting margin: lip heart-ſhaped, with a ſmall recurved point, purpliſh but not ſtreaked. The colour of the flowers is very variable: they have generally a faint, aromatic, orchis-like ſmell. The germ and ſtem are more or leſs downy [o].

Mr. Woodward remarks, that the lower leaves are ovate, two inches and a quarter broad, and not more than three or four inches long; the germ pear-ſhaped and ſhort: and Dr. Withering—that the ſtem is more or leſs of a browniſh purple; the ſpike from three to eight inches long, with from ſix to twenty flowers or more, much cloſer ſet than in the next ſpecies; calyx-leaves three, browniſh green, broad ſpear-ſhaped, keeled; the two lateral petals reſembling the leaves of the calyx, purpliſh green; the upper lip of the nectary glandular, white, fleſhy, the lower diſtended at the bottom into a nearly globular hollow, purple within and of a browniſh green without, towards the end flat purpliſh and ſomewhat ſcolloped: anthers yellowiſh white, connected to their caſe by a milk-white globular ſubſtance: piſtils two white fleſhy, fixed on the glandular receptacle: capſule obovate, bulging on the upper ſide, ſmooth or nearly ſo.

Native of Europe, in woods, groves and hedges; flowering in july and auguſt. Not uncommon in Britain, eſpecially in the mountainous parts: as in the north-riding of Yorkſhire, about Matlock, &c. In Derbyſhire, Buckham wood in Cumberland, in the red rock plantation, Edgbaſton Park. In Scotland, at Chatelherault near Hamilton, and in the wood of Comrie in Strathearn: but not very common. Alſo in the midland and other countries of England, as Kingſton wood in Cambridgeſhire, Thurleigh and Sheerhatch in Bedfordſhire, Northleigh and Stokenchurch woods in Oxfordſhire, about Oſpringe in Kent, Buddon wood and about Loughborough in Leiceſterſhire, Broadly and Clenſton woods in Dorſetſhire, and Selborne in Hampſhire, &c. In Ireland, in Lord Dungannon's plantations at Belvoir.

Mr. Hudſon's variety β. Helleborine altera atro-rubente flore. *Bauh. pin.* 186. *Ray ſyn.* 383. differs only in not being ſo tall, the fibres of the root very long and tough owing to its ſituation, the leaves ſmaller; the lower ovate pointed not obtuſe, and the outer appearance of the flower a darker colour. Mr. Ray ſays, the leaves are narrower and more frequent on the ſtem, and that the flowers, which are of a blackiſh red, come out later. He found it near Malham, four miles from Settle in Yorkſhire, and in other mountainous ſituations. Mr. Woodward, who furniſhed the above obſervations, gathered it on Conzick Scar, four miles from Kendal, growing at the foot of the Scar itſelf among the looſe ſtones and rubbiſh, in a ſituation not acceſſible without difficulty and danger.

2. Root creeping, fleſhy, perennial. Stem erect, ſimple, from twelve to eighteen inches high. Lower leaves ovate, often purple at the back; upper lanceolate, erect; all embracing and ribbed. Spike erect. Bractes lanceolate, about equal to the germ. Flowers fewer and much larger than in the preceding ſpecies, drooping, with downy purple peduncles and germ. Petals rather obtuſe, the three outer green, the two inner white, all ſtreaked and ſtained with purple. Nectary about as long as the petals, white ſtreaked with purple, and a yellow central line; lip heart-ſhaped, with a dilated waving crenate margin, and a notched protuberance above the baſe [p].

Germ, according to Mr. Woodward, long, narrow, and when full grown elliptical, eight lines long and four broad, with ſix prominent ridges. Lip of the nectary divided tranſverſely almoſt through, the upper part fixed and boat-ſhaped, marked with red ribs, and at the bottom a yellow line with orange ſpots, the lower part hangs down and is white.

Mr. Wood remarks, that the outer half of the lip is ſo ſlightly attached as to be ſhaken off by a ſmall motion, and is often blown off by the wind while the plant is growing:—Mr. Hollefear, that the leaves are ſometimes ovate-lanceolate with ſeven ribs:—Dr. Stokes, that they are ſometimes ovate-oblong and blunt; the peduncles downy and filiform; the germs downy, ſlightly ſcored, long, tapering down to the peduncle, and a little towards the point:—Dr. Withering, that the ſpike is about four inches long, with from ſix to twelve flowers, much wider ſet than in the preceding ſpecies; peduncle and germ woolly, the latter uniform, not bulging on the upper ſide.

The characters thus detailed leave no doubt of this being a diſtinct ſpecies from the preceding: the different lengths of the lip, and the ſhape of the germs will always diſcriminate them; and ſhould the woollineſs of the peduncle flower and germs be conſtant in this, and always wanting in that, their difference will be obvious at firſt ſight [q].

Native of Europe, in ſwampy meadows, watery places, marſhes, moraſſes and bogs. In England not very unfrequent; as on the bogs of Chiſelhurſt in Kent, in Eſſex, Norfolk, Cambridgeſhire, Bedfordſhire, Oxfordſhire, Leiceſterſhire, near Leeds in Yorkſhire, on the borders of Malvern Chace, Worceſterſhire, near Sturminſter Newton and between Wimbourne and Ringwood, Dorſetſhire, and on Knutsford Moor, Cheſhire. Near Duntulm caſtle, in the iſle of Skye, in Scotland.—In Ray's ſynopſis it is ſaid, on the authority of Mr. J. Sherard, to be very common in the old chalk-pits by the White-houſe, in the road from Eltham to North Cray, with the Orchis myodes, on chalky ground: but ſurely that muſt be a miſtake, ſince it is not found any where elſe in ſuch a ſituation.—Mr. Hudſon's aſſertion, that this, if planted in a garden or dry ſoil, will the ſecond year become S. latifolia, looks like another miſtake.

3. This has moſt affinity with the *grandiflora*, and has often been confounded with that; the root however ſeems to be not ſo properly creeping, but conſiſts of a bundle of long fleſhy fibres. Leaves long and ſword-ſhaped, ſtanding almoſt in two ranks, the uppermoſt nearly linear, the loweſt very blunt and even emarginate. Bractes extremely ſmall, except the lowermoſt, ſcarcely a quarter ſo long as the germ, by which this ſpecies is eſſentially diſtinguiſhed. Flowers white, upright. Germ ſlender, ſtriated: the lip has white

[o] Engl. bot.

[p] Idem. [q] Wither. arr.

Digitized by Google

elevated ribs running longitudinally, and in the front a yellow creſcent-like ſpot [r].

According to Ray, the root is compoſed of many thickiſh fibres; the ſtem a foot high or more, and upright. Root-leaves long, narrow, pointed, reſembling thoſe of reeds; ſtem-leaves very many, narrow. Flowers ſnow-white, eight or ten, in a looſe ſpike.

Mr. Woodward deſcribes the ſtem as a foot high, ſometimes ſlightly twiſted. Stem-leaves bright-green, ſmooth, ſhining, having five or ſeven principal ribs; the longeſt ſix inches long, and half an inch wide; the lower embracing, the upper ſeſſile, alternate, and pointing from two oppoſite lines. Seed-veſſels upright, elliptical, but from the projecting ribs appearing three-cornered, longer and narrower than thoſe of paluſtris [s].

Native of ſeveral parts of Europe. Found by Newton under Brackenbrow or Brackenwray, oppoſite Helk's wood a mile from Ingleton in Yorkſhire. Dr. Richardſon obſerved it there afterwards [t]:—by Mr. Woodward in Lord Lonſdale's woods at Lowther in Weſtmoreland:—by Walter Michael Moſely, Eſq. of Glaſhampton, on the top of Aberly hill in Worceſterſhire, and alſo in Wire foreſt in the ſame county [u]. Sherard found it in a rotten bog by a lough-ſide near the dairy-houſe in Crevetenau Ballinahinch, Ireland, and communicated it to Ray in 1694. Eales afterwards ſent it to him from Hertfordſhire [x]. But was not this rather the grandiflora?

4. Root long and creeping, perennial. Stem about a foot high. Leaves ribbed, various in breadth, but generally rather elliptical than lanceolate, their baſe half embracing the ſtem. Spike erect, with from three to eight large white nearly upright flowers. Lower bractes like the leaves in form and ſize, the others gradually leſs, but none ſhorter than the germ, which is ſlender and deeply furrowed. Petals but little expanded, and encloſing the lip of the nectary, which is heart-ſhaped, obtuſe, entire, with three elevated longitudinal yellow ribs on the upper ſide [y].

Native of Europe in woods and thickets. It occurs with us chiefly in the midland counties. In Stokenchurch woods, and Shotover plantations in Oxfordſhire. About Marlow in Buckinghamſhire. In Glouceſterſhire. In Mr. Knight's walks, Wolverley, Worceſterſhire. In Purbeck, in the woods at Grange, and in the lane going up the hill above; in the grove at the Down-houſe near Blandford, and in Little wood at Chettle in Dorietſhire. Teverſham and Quey in Cambridgeſhire and the Iſle of Ely. In Lord Lonſdale's wood, againſt Aſkham-hall, Weſtmoreland. In Scotland, but rarely: in a wood at Loch Ranſa, in the Iſle of Arran. It flowers in june.

5. Roots brown, flexuoſe, numerous. Leaves acute, nerved, embracing. Bractes ſmall, awl-ſhaped. Corollas white: ſegments lanceolate, converging; lip ſhorter by half than the petals, channelled, blunt, ſtriated.—It differs from *grandiflora*, in having a cloſer ſpike, ſmaller bractes, and flowers only half the ſize. Native of Algiers, on hills [z].

6. Native of Jamaica and Hiſpaniola.

7. Native of Jamaica [a].

8. Root creeping horizontally, and producing many long ſimple fibres. Stem perfectly erect, a foot high, leafy, downy, compreſſed, having fewer leaves on the upper part. Leaves a little ſpreading in various directions, pointed and ribbed. Spike of from three to ſix purple flowers. Bractes lanceolate; the loweſt ſometimes as long as its correſponding flower; the reſt little longer than the germ, ſometimes rather ſhorter. Germ ſlender, downy. Petals all directed upwards, ovate, very much pointed. Nectary with a ſhort blunt projection behind; its lip about equal to the petals in length, white tipped with purple, lobed on each ſide at the baſe, marked with yellow elevated waving lines, and terminating in a ſharp point.

Native of Europe. Plukenet received it from Ireland; and on his authority, Dillenius inſerted it in his edition of Ray's ſynopſis. Hudſon ſays that it grows about Clapham and Ingleton in Yorkſhire. Dr. Withering, in the third edition of his Arrangements, conſiders it as a doubtful native of our iſland. It was however gathered in june 1800 on a ſteep ſtony bank on Hampton common, Glouceſterſhire, by Mrs. Smith of Barnham Houſe; and in the following month, by the Rev. Mr. Baker, in another part of the ſame county [b].

Much confuſion reigned among the four Britiſh ſpecies of Serapias, till Lightfoot, Withering, and Smith, aſcertained and diſtinguiſhed them ſatisfactorily.

9. Bulbs three, four or more, roundiſh, villoſe, hanging down from the ends of the fibres. Leaves narrow-lanceolate, acute, channelled. Stem clothed with ſheaths of leaves. Flowers two to four, in a looſe ſpike. Bractes lanceolate, acute, concave, erect, purpliſh, longer than the germ. Petals three, lanceolate, acute, converging, concolor, marked with lines. Lip ſtanding out, three-lobed; the two ſide-lobes ſhort and rounded; the middle-lobe ſmooth, lanceolate, acute, quite entire.—This is allied to the next ſpecies, but differs in having the flowers in ſpikes, and little more than half the ſize, with the lip lanceolate not cordate [c].

Native of France, Switzerland, Carniola, Italy, and Africa near Algiers. Introduced in 1786, by Sir Francis Drake, Bart. It flowers in may [d].

10. Bulbs commonly many, ſpherical, two of them approximating as in ſome of the Orchiſes; the reſt hanging from the ends of the fibres. Leaves narrow-lanceolate, acute, channelled, involving the ſtem. Flowers three to ſix, looſe, terminating, ſubpanicled. Bractes concave, lanceolate, acute, longer than the germ, purpliſh, with longitudinal veins of a deeper colour. Petals three, concolor, converging, lanceolate, acute. Lip excavated at the baſe, deep purple, three-lobed, the ſide-lobes ſhort, rounded, the middle lobe very large, ſubcordate, acuminate, veined, quite entire, villoſe, but ſometimes ſmooth [e].

It reſembles the preceding, but is larger. The lip of the nectary is ſubcordate, and bearded at the baſe in the middle, with an erect obtuſe earlet on each ſide [f].

Native of Spain, Italy, the Levant, and Africa about Algiers; flowering early in the ſpring.

11. Stem a foot high, erect, quite ſimple, even. Root-leaves ſword-ſhaped, folded together, even, a finger's length, acute: ſtem-leaves alternate, remote, ſheathing, oblong, acute, an inch in length. Raceme terminating, quite ſimple, directed one way: flowers eleven or twelve, each on a ſeparate peduncle. Bractes lanceolate, membranaceous, ſhorter than the flower. Petals five, lanceolate, even, erect. Lip of the nectary bifid.—Native of the Cape of Good Hope [g].

12. Stem erect, ſubflexuoſe, angular, ſmooth, a ſpan high. Leaves about five, alternate, embracing: the two lower ſheath-form; the two middle ovate, acute, entire, nerved, ſmooth, from upright ſpreading, an inch long; the uppermoſt lanceolate, nerved. Flowers terminating, in a ſpike, erect, white, ſmall.—Native of Japan.

13. Stem covered with ſheathing leaves, a ſpan high. Leaves acute, nerved, entire, ſmooth, a finger's length, about five. Flowers terminating, in a ſpike erect.

Native of Japan, on the mountain Fakona; flowering in april [h].

14. Spathes lanceolate, acute. Petals ſix, ovate-lanceolate, ſpreading, concave, the three outer larger. Nectary one-leafed, two-lipped: upper lip truncate, very ſhort; lower erect, trifid, the middle ſegment cowled, the lateral ones ſlender with a radiant beard at the point.—Native of New Zealand [i].

Forſter firſt made this plant a diſtinct genus under the name of *Thelymitra*, the parts of fructification having a covering like a woman's hood or bonnet; but afterwards, by the perſuaſion of Solander, he reduced it to this genus.]

PROPAGATION AND CULTURE.

These plants being difficult to preserve and propagate, few have attempted to keep them in gardens. They may be taken up from the places where they grow naturally when their leaves begin to decay, and planted in a shady moist place, where they will thrive and flower.

[See Ophrys and Orchis.

Serapias. See *Arethusa*, *Cypripedium*, *Ophrys*, and *Orchis*.

Seriana or Seriania. See *Paullinia*.

SERIOLA. (*A little vessel, jar or pot.*)

Lin. gen. n. 917. *Reich. n.* 996. *Schreb. n.* 1245. *Gærtn. t.* 159. *Juss.* 171. Achyrophorus. *Vaill. act. gall.* 1721. *f.* 28. 13. 21. 18.

Class. 19. 1. Syngenesia Polygamia Æqualis.

Nat. order of *Compositæ Semiflosculosæ. Cichoraceæ*, Juss.

GENERIC CHARACTER.

Cal. *Common* simple: *leaflets* linear, almost equal, erect.

Cor. *Compound* imbricate, uniform. *Corollets* hermaphrodite, equal, numerous.

Proper one-petalled, ligulate, linear, truncate, five-toothed.

Stam. *Filaments* five, capillary, very short. *Anther* cylindrical, tubulous.

Pist. *Germ* ovate. *Style* filiform, length of the stamens. *Stigmas* two, reflex.

Per. none. *Calyx* unchanged.

Seeds oblong, length of the calyx. *Pappus* capillary, stipitate; with ten rays, hairy at the sides.

Rec. chaffy, length of the calyx, deciduous.

ESSENTIAL CHARACTER.

Cal. simple. *Pappus* subplumose. *Recept.* chaffy.

Hieracium alpinum, &c. *Cup. cathol.* 95. *Raii suppl.* 146. *n.* 89.

Stinging, leaves toothed, stem branched.

DESCRIPTIONS, &c.

1. Roots perennial, long, twisted, the thickness of the little finger, covered at top with brown scales from the withered petioles. Leaves radical, smooth, remotely toothed, obovate or spatulate, decurrent. Scape erect, slender, smooth, very slightly streaked, sparingly branched and sometimes quite simple, almost leafless. At the base of each branch is an awl-shaped leaflet or scale. Peduncles almost filiform, few (three or four) unequal, one-flowered. Calyx smooth, cylindrical; with the outer leaflets few and shorter; the inner linear and equal. Petals yellow, linear, toothed at the end, twice as long as the calyx. Seed brown, smooth, slender, elongated. Pappus simple, nutescent, sessile in the ray, stiped in the disk [k].

Vahl describes the root as woody, fusiform, divided at top; the leaves collected into a rose, wedge-form, ending in a channelled petiole, an inch and half long, mostly quite smooth, even, (sometimes, but very seldom, having a few hairs on the upper surface towards the point,) glaucous-green, veinless, sharpish, having three or four distant teeth on each side. Calyx subimbricate, with the outer leaflets short and unequal, the inner towards the point having a hispid line of hairs. Seeds awl-shaped, appearing to be transversely streaked when examined with a magnifier. Pappus eight or ten-rayed, subplumose. Chaffs membranaceous, linear, acuminate.

Native of the island of Candia, and of Barbary, in the clefts of rocks. Introduced in 1772, by Monsr. Richard. It flowers in july and august [l].

2. Root annual. Stems branched, erect, hirsute. Leaves villose, obtuse, remotely toothed: upper stem-leaves sessile, embracing. Peduncles long, erect, one-flowered, hispid, leafless above, unequal, panicle-corymbed. Calyx simple or scarcely imbricate, cylindrical, very hirsute, with linear leaflets. Corolla yellow. Seeds even, those of the ray naked. Pappus of the others feathered, stiped. Chaffs linear, acute, deciduous [m].

Receptacle, according to Gærtner, convex, covered all over with membranaceous, linear-lanceolate, deciduous chaffs, nearly equal to the calyx. Seeds small, fusiform, striated, rugged with sharp points, of a red-rust colour. Pappus feathered, permanent, stiped, having about ten white rays between chaffy and bristly: stipe capillary, length of the seed.

Native of Italy, and of Barbary near Mascar.

3. Native of the island of Candia or Crete.

4. The scales of the calyx are sharp with pungent spinules [n]: which, says Ray, distinguishes this plant at first sight. He adds, that there is a long narrow leaf at the origin of each branch.

Native of Sicily and other parts of the South of Europe. This and the second species were introduced by John Earl of Bute, the former in 1771, the latter in 1773 [o].

SERIPHIUM. (Σεριφιον *of Dioscorides.*)

Lin. gen. n. 1003. *Reich. n.* 1087. *Schreb. n.* 1358. *Gærtn. t.* 167. *Juss.* 180. Helychrysoides. *Vaill. act. gall.* 1719.

Class. 19. 5. Syngenesia Polygamia Segregata.

Nat. order of *Compositæ Nucamentaceæ. Corymbiferæ*, Juss.

GENERIC CHARACTER.

Cal. *Outer Perianth* of five roundish imbricate tomentose leaflets.—*Inner* of five erect acuminate awl-shaped very smooth scarious leaflets, twice as long as the others; one-flowered.

Cor. one-petalled, funnel-form, shorter than the inner calyx: *border* five-toothed.

Stam. *Filaments* five, capillary. *Anther* cylindrical.

Pist. *Germ* inferior to the corollet, superior to the calyx. *Style* filiform. *Stigma* subbifid.

Per. none. *Calyx* unchanged, closed.

Seed solitary, oblong.

ESSENTIAL CHARACTER.

Cal. imbricate. *Cor.* one-petalled, regular. *Seed* one, oblong, below the corolla.

Flowers in ſpikes three-flowered, leaves linear.

DESCRIPTIONS, *&c.*

1. Branches in whorls. Leaves lanceolate, ſmall, cluſtered, recurved, gibbous at the baſe, hoary. Spikes fox-tail like, pale red, interrupted. Scales of the calyx almoſt ſetaceous[p].—General calyx none, or not diſtinct from the outer chaffs of the receptacle: partial one-flowered, double, each five-leaved: outer leaflets ſhorter, tomentoſe, obtuſe, like the chaffs equal; inner longer, ſcarioſe, ſmooth, briſtly-acuminate, unequal, prominent far beyond the chaffs, ſo as to form an echinated head. Florets cylindric-funnel-form, five-cleft. Common receptacle ſubglobular, covered all over with ovate-oblong, concave chaffs, tomentoſe on the outſide. Seed ovate-globular, five-grooved, ſmooth, ſmall, of a pale whitiſh colour. Pappus the length of the corollet, caducous, with about twelve rays, pencil-feathered at top, naked at bottom, ſetaceous, united in a ring[q]. Introduced in 1774, by Mr. Francis Maſſon. It flowers from july to ſeptember[r].

2. Flowers five or ſix-flowered. Leaves filiform. Flowers lateral, ſeſſile, imbricate with granulate leaves[s].

3. Flowers one-flowered, terminating, ſeſſile, in bundles. Stems diſtorted, branched, flexuoſe. Leaves cinereous, awnleſs[t].

4. This is a procumbent, cinereous ſhrub. Leaves ſimple, linear, cluſtered. Spikes long, terminating the branches. Flowers roundiſh. Calyxes cinereous, but with the inner row of ſcales ſcarioſe or membranaceous, coloured, white as in the Gnaphaliums. Four or five capillary rays, the length of the florets, feathered at the point, ſtand round the florets. Seeds naked.

This ſpecies is intermediate between the Seriphiums, Artemiſias, Gnaphaliums and Stoebes. It naturally appertains to this genus, though it is not without difficulty combined with it, except in the pappus feathered at the point[u].

All the ſpecies are natives of the Cape of Good Hope.

Leaves ſeſſile pinnatifid ſpiny, ſtem panicled, calyxes ovate ſpinuloſe.

DESCRIP-

Digitized by Google

DESCRIPTIONS, &c.

1. Root perennial, ſomewhat woody. Stem erect, ſtiff and ſtraight, two or three feet high, leafy, angular, ſmooth. Leaves alternate, lyrate or variouſly pinnatifid, (ſometimes undivided;) the root-leaves commonly entire; all acutely ſerrate and minutely ciliate, rigid, ſmooth on both ſides. The whole plant is firm, rigid and hard to the touch, but not prickly. Flowers corymbed, of a blood-red purple colour, ſometimes varying to white. Scales of the calyx duſky, purple, ſometimes villoſe, the outer ones gradually ſmaller. Receptacle briſtly. Seeds ſtriated. Pappus unequal, yellow, rugged on one ſide, recurved at the point[y]: ſhining, ſays Gærtner, with gold colour and brown; the rays ſetaceous, ſtiffiſh, ſcarcely at all, or very minutely toothletted.

Native of Europe, in woods, thickets, hedges and buſhy paſtures; flowering in july and auguſt. Linneus ſays, it is much uſed in Sweden as a yellow dye for coarſe woollen cloths; whence he gave it the name of *tinctoria*. Materials for that colour are ſo abundant, and moſt of them ſo ſuperior to this, that it is probably not uſed in England[z].

2. This is ſo like the preceding as ſcarcely to be diſtinguiſhed from it, except by its being three times the ſize, having a grooved ſtem, twice as many florets, and a declining leaf under the calyx; but eſpecially in having a ray, with tubular, narrower, female, fertile florets.

The genus is doubtful: the female ray ſhould indicate it to be a *Centaurium*, but the fertility of theſe florets, and the whole habit of the plant are repugnant. If ſeveral of the ſpecies were like this, it would be worth while to form a new genus for them, but this one ſcarcely merits it[a].

Native of Italy, Sileſia and Siberia. Cultivated in 1748, by Mr. Miller. It flowers in july and auguſt[b]. This ſpecies is omitted in the later editions of Mr. Miller's dictionary.

3. Stem angular, grooved, rugged, erect, three feet high. Leaves ſcattered, petioled, acute, toothed, green above but aſh-coloured beneath, muricate-ſcabrous on both ſides, a finger's length, the upper ones gradually leſs. Flowers terminating, panicled. Panicle faſtigiate, decompounded. The inner ſcales of the calyx are widened at the end, blunt and fleſh-coloured.

Native of Japan[c].

4. Roots ſlender, though tough and woody, perennial, black on the outſide. Stems ſimple, upright, leafy, round, ſtriated, cottony, various in height, generally ten or twelve inches, (about five inches, *With.*) Leaves ſcattered: the root-leaves and lower ſtem-leaves petioled, the upper ones ſeſſile: various in form, but generally ovate, ſometimes linear-lanceolate, ſometimes almoſt haſtate, always more or leſs toothed, ſmooth above, cottony and white beneath: ſix or ſeven in number, according to Dr. Withering. Flowers corymbed, (eight to twelve,) erect, purple with blue anthers, and handſome, terminate the ſtem. Scales of the calyx ſoft, blunt, purpliſh-brown, ſilky with white hairs. Seed-down equal, elegantly feathered[d].

Native of the high mountains of Lapland, Norway, Auſtria, Switzerland, Sileſia, Siberia, Wales and Scotland. Johnſon, the editor of Gerarde, ſeems firſt to have obſerved it in Britain; after him, Edward Lhwyd, on Snowdon and other high mountains in North Wales. (See Merret's Pinax, and Dill. elth.) J. W. Griffith, Eſq. has lately found it on the higheſt rocks of Caernarvonſhire; flowering in july and auguſt. It appears from Lightfoot, that it is not very rare in Scotland. According to Merret, it grew on Brearcliff near Brunley, Lancaſhire.

Linneus remarks, that place does not ſuffice to produce all the conſtant varieties of the leaves. Dr. Smith, on the contrary, is perſuaded, from obſervations made upon the ſpot, that they are mere varieties occaſioned by local accidents.—The figures in *Hortus Elthamenſis* and *Flora Danica*, repreſent the narrow-leaved taller variety[*].

5. Stem angular, branched at top as in its congeners. Leaves like thoſe of the Willow, ſcarcely or at all decurrent at the baſe. Flowers red. Calyxes of the ſame appearance as in *S. alpina*, three or four on each branch.—Native of Siberia[†].

6. Stem angular, corymbed, with the branches again corymbed, ſo that it is terminated by a prodigious cloſe wood of flowers. Leaves like thoſe of the Willow, clothed with a white nap beneath. Calyxes cylindrical, with ſmooth, acute, purpliſh ſcales. It is like the preceding, but the leaves are a little decurrent at the baſe and villoſe beneath, and the calyxes are more abundant, ſharper, ſmoother and brighter coloured[e].

Stem, according to Loureiro, ſuffruticoſe, three feet high, erect. Leaves wide-lanceolate, ſerrate-lyrate, ſmooth, ſcattered. Flowers many, ſmall, red, on terminating, faſtigiate peduncles. Calyx cylindrical; ſcales imbricate, ſhort, cloſe, awnleſs, converging at the point. Corollets very ſmall. Receptacle lanuginoſe. Seed-down ſilky white, with rays in ſeveral rows linear-chaffy, ciliate, unequal[f].

Found in Siberia by Gmelin, in Sileſia by Krocker, in China near Canton by Loureiro.]

7. Root perennial. Stalks ſeveral, channelled, ſeven or eight feet high. Leaves from four to five inches long, and one inch broad in the middle, ſlightly ſerrate, downy on their under ſide, ſeſſile. The upper part of the ſtalk divides into peduncles, ſuſtaining purple flowers, which appear at the end of july.

Native of North America. [Cultivated by James Sherard, M. D. in 1732[g].

Dillenius ſays that it grows ten or twelve feet high; that the umbel or corymb of flowers has fewer heads in it and is leſs ſcattered than in the *glauca*, ſmall in compariſon with the ſize of the plant; that the ſcales of the calyx are narrower, and end in ſlender oblong horns; and that by theſe marks, with its great height, and very long rough pendulous leaves, it is eaſily diſtinguiſhed. It flowers very late alſo, namely about the end of october. In the Kew catalogue it is ſaid to flower from ſeptember to november.]

8. Root large, perennial, fibrous. Stem branching, from four to ſeven or eight feet high. Leaves ſeven inches long, and an inch and half broad in the middle, ending in acute points, entire, hairy on their under ſide, ſeſſile. Flowers in looſe bunches at the end of the branches. Calyxes oval, compoſed of few ſcales terminating in briſtles. Flowers pale purple.

[Stem ſtraight, ſimple, deeply ſtriated, tinged with red, ſmooth or ſcarce ſenſibly hairy. Leaves alternate, frequent, ſhorter and leſs wrinkled than in the preceding ſpecies, more widening in the middle, not pendulous, either ſpreading horizontally or obliquely upwards, leſs ſerrate than in that, but minutely toothletted, yelloviſh green above, more lanuginous and hoary beneath than in *noveboracenſis*. The flowers are like thoſe of the preceding, and the heads are diſpoſed in the ſame manner, but are ſomewhat rounder, and the cuſps or points at the ends of the calyx-ſcales are not ſo long. The receptacle is naked. It flowers about the ſame time with the preceding ſpecies; and is a native of Virginia, Carolina[h], Penſylvania, and moſt other parts of North America. Cultivated in 1732, by James Sherard, M. D.[i].

The trivial names of theſe two ſpecies are by no means ſignificant; the ſeventh being tall, and the eighth having long leaves; the latter is probably found in New York as well as the former, and trivials from place are at beſt bad ones, for the moſt part.]

9. Root perennial. Stalks ſix or ſeven feet high, purple and channelled. Leaves about three inches long, and an inch and half broad in the middle, ending in acute points, ſtiff, ſerrate, and of a light green on both ſides. Flowers in a looſe terminating corymb, purple with roundiſh calyxes.

[Stems ſtraight, ſtriated, ſmooth, not ſo high as the *noveboracenſis*, branched only at the top, but there

[y] Smith. [z] Engl. bot. [a] Linn. ſpec. [b] Hort. kew. [c] Thunberg. [d] Smith.

putting forth flowering-branches a foot or eighteen inches in length, divided and ſubdivided into many branchlets and peduncles. Calyxes duſky purple. Corollets dark purple verging to violet. Seed-down browniſh white, very prominent. Receptacle naked. Leaves dark glaucous green above, paler and glaucous beneath, with fine hairs along the midrib and veins, in other parts ſmooth.

Native of Maryland, Virginia and Carolina. It flowers in october. Cultivated at Eltham in Sherard's garden in 1732[k].]

10. Root tuberous, from which comes out a ſingle ſtalk, riſing near three feet high. Leaves ſtiff, about three inches long, entire, rough to the touch, pale green on both ſides. The upper part of the ſtalk is adorned with purple flowers, having oblong, rough, prickly calyxes, coming out from the ſide alternately; and the ſtalk is terminated by one head larger than the others.

[Root-leaves in a ring, a foot long, half an inch broad, rigid and nerved. Stems ſeveral, ſimple, from two to three feet high, thinly pubeſcent. Stem-leaves frequent, alternate, reflex, rigid, nerved, ſtraight-veined, ſubhirſute, reſembling thoſe of *Tragopogon*, but neither ſo pointed nor embracing. Peduncles an inch long, alternate from the upper axils. Heads of flowers ſquarroſe or compoſed of leafy ſcales ſtanding out and bent back, keeled and ſomewhat hairy. Florets recurved, purple. Styles very long. Seeds oblong, ſtriated, crowned with a feathered down. Receptacle naked[l].

Native of Virginia, and moſt of the provinces of North America.—Cultivated in 1732, by James Sherard, M. D. It flowers in july and auguſt[m].]

11. This has a large tuberous root, from which comes out one ſtrong channelled ſtalk, three or four feet high. Leaves frequent, about three inches long, and half an inch broad. Flowers purple, in a long looſe ſpike, coming out from the ſide upon pretty long blunt peduncles; they have large rough calyxes compoſed of wedge-ſhaped ſcales. The upper flowers blow firſt, and appear in auguſt.

[It is very diſtinct from the preceding, by its ſquarroſe blunt calyxes; lateral, elongated, one-flowered peduncles, having a few leaflets on them; wide-lanceolate leaves, by no means nerved, ſeſſile but not decurrent[n].

Native of Virginia. Cultivated by Mr. Miller in 1759[o].

12. Native of North America. Introduced in 1783 by Mr. William Young. It flowers in ſeptember and october.

13. Native of Carolina and Georgia. Introduced in 1787, by Meſſ. Watſons. It flowers in october[p].]

14. This has a tuberous root, from which comes out a ſingle ſtalk from two to three feet high. Leaves very narrow, ſmooth, at bottom more than three inches long, but gradually diminiſhing to the top, ſeſſile, and placed round the ſtalk without any order. Flowers purple, ſmaller than in the tenth and eleventh ſorts, ſeſſile, and forming a long looſe ſpike.

[Native of North America. Cultivated in 1732, by James Sherard, M.D. It flowers from auguſt to october[q]. Baniſter firſt obſerved it in Virginia[r].

15. This has the habit of *S. alpina*. Leaves ſomewhat decurrent, the upper ones quite entire, rugged, eſpecially at the edge. Stems angular. Branches erect, each commonly terminated by three peduncles and flowers. Calyxes membranaceous, ſoft as in ſome *Centaureas*. Seed-down white.

Native of Siberia[s].

16. Herb a foot high. Branches alternate, ſtiff, almoſt ſmooth, one-flowered. Leaves ſmooth on both ſides, veined, lanceolate; with lanceolate teeth, vertical or turning their upper ſurface not towards the ſky but ſideways, as in *Lactuca Scariola*. Calyx ovate-oblong, imbricate with ſcales having a harmleſs point; thoſe which are nearer to the florets larger and dried up. Corolla purple, without any marginal florets. Style twice as long as the florets. It has the habit of *Centaurea moſchata*, but has no neuter florets[t]. Seed-down of a whitiſh ſtraw colour and ſhining, with very numerous unequal linear chaffy rays, very cloſely toothletted ciliate[u].—Native of Siberia.

17. Plant very ſmooth. Stem erect, ſlender, deeply ſtriated, naked at top, ſimple or ſometimes but ſeldom divided into two or three unequal, one-flowered branches. Leaves quite entire or ſometimes toothletted, above even and ſhining; the lower ones ovate-lanceolate, running along the petiole; the upper ſtem-leaves ſeſſile, acuminate. Calyx ovate, cloſely imbricate, with lanceolate ſcales, having a rigid ſcarioſe point, a little bent back. Corollets roſe-coloured, or inclined to violet. Seed oblong, ſmooth, ſtriated, with a ſimple, ſeſſile down. Receptacle hairy.

Native of Barbary, near Maſcar, flowering early in the ſpring.

18. Root twiſted, brown without, the thickneſs of a gooſe quill. Pinnules of the leaves diſtinct, uniform, lanceolate, acute or obtuſe, quite entire, but ſometimes toothed at the baſe. Petiole winged. Stem erect, ſtriated, tomentoſe, leafy but ſometimes naked. Calyx cylindrical; leaflets almoſt equal, ſtiffiſh, in three or four rows. Florets roſe-coloured. Seed ſmooth, ſtriated, oblong; with a long, whitiſh, ſeſſile, ſubplumoſe down. Chaffs of the receptacle acuminate, lacerated at the point. It is a very handſome ſpecies; and flowers in the ſummer.

Native of mount Atlas near Tlemſen[x].—If this be the *mollis* of Cavanilles, it is alſo a native of Spain, in the kingdom of Valentia. His figure and deſcription agree with thoſe of Desfontaines, but he marks it as annual, whereas according to the latter it is perennial.

19. Stem herbaceous, perennial, a foot and half high, half procumbent, round, thickiſh, with few branches. Root creeping far and wide. Leaves ſharply and deeply ſerrate, unarmed, tomentoſe beneath, ſhining above, juicy, ſtrong-ſmelling, half embracing. Flowers terminating, purple: calyx ſubcylindrical, imbricate, even, few-flowered. Receptacle naked. Seeds oblong, ſurrounded by their proper involucre, and crowned with a hairy ſeſſile down.—Native of China and Cochinchina[y].

20. The common creeping Thiſtle or Way Thiſtle, which Linneus has placed in this genus, but Curtis and Dr. Smith, with more propriety, in that of *Carduus*, where from its habit moſt of the old authors had put it, is too well known by its perennial creeping root. Stems three feet high or more, upright, leafy, at the baſe round and ſomewhat woolly, above angular and ſmooth, panicled and many-flowered at top. Leaves alternate, ſcarcely decurrent; ſmoothiſh; lobes unequal, ciliate and ſpiny. Flowers ſingle, ſometimes two together on a leafy peduncle, which is ſomewhat woolly at top; they are pale purple, varying to white. Calyx ovate, with wide-lanceolate-ſcales, preſſed cloſe, woolly at the edge, pointed with ſhort ſpreading ſpines. Seed-down feathered, deciduous, very long. Receptacle hairy[z].

This Thiſtle is known every where by road ſides, too frequently in corn-fields, eſpecially in ſtrong land, and in paſtures, but not ſo common there; flowering from june to auguſt. It has certainly the habit of the Thiſtles, though Linneus has made it a *Serratula*; and, as Mr. Curtis remarks, if the Marſh Thiſtle be a *Carduus*, this alſo muſt be one, the ſtructure of the fructification being the ſame in both.

It is one of the worſt peſts of arable lands, having ſtrong creeping roots, ſtriking down to a great depth, and then branching out horizontally, ſo that it is very difficult to root it out where it has once got poſſeſſion, and every ſmall piece of it will grow. Some idea of its increaſe may be formed from the following experiment, which was made by Mr. Curtis. "I "planted in a garden a piece of the root of this "Thiſtle, about the ſize of a gooſe quill, and two

[k] Dill. elth. [l] Idem. [m] Hort. kew. [n] Linn. ſpec. [o] Hort. kew. [p] Idem. [q] Idem. [r] Hort. elth. [s] Linn. ſpec. [t] Idem. [u] Gærtner. [x] Desfontaines. [y] Loureiro. [z] Smith brit. and Fl. ruſt.

Digitized by Google

" inches long, with a ſmall head of leaves, cut off " from the main root, as it was ſpringing out of the " ground. This was done on the firſt of april: by " the ſecond of november following this ſmall piece " had thrown out ſhoots, ſeveral of which had ex " tended themſelves to the diſtance of eight feet; " ſome had even thrown up leaves five feet from the " original root; moſt of the ſhoots were about ſix " inches under ground; others had penetrated to the " depth of two feet and a half: the whole together, " when dug up and waſhed from the earth, weighed " four pounds. In the ſpring following, it again made " its appearance on or about the ſpot where the ſmall " piece was originally planted. There were between " fifty and ſixty young heads, which muſt have ſprung " from the roots that had eluded the gardener's ſearch, " though he was particularly careful in extracting " them."

Frequent and deep ploughing in dry weather will deſtroy this thiſtle in arable land; but common ploughing is not deep enough to anſwer the purpoſe. In paſtures it ſhould be pulled or rather forked out, when the ground is well ſoaked with wet. Mr. Curtis affirms that repeated mowing or ſpudding, if they do not effectually overcome, will greatly enfeeble it: they ſeem however to make it run more at the root: but to prevent it from flowering is ſomething. Some perſons are perſuaded that mowing it down when it is in full flower, is the moſt effectual way to deſtroy it: Monſ. Villars recommends laying down land infeſted with this thiſtle, with artificial graſſes. I have tried all theſe methods without complete ſucceſs. A piece of land which I laid down with broad and dutch Clover, after Turneps well hoed, is now overrun in ſome parts with this curſed thiſtle, as Mr. Curtis names it. And after all our pains, the magazines which are left to ſeed by road ſides, will always ſupply a freſh crop.

The goat and aſs will eat it; horſes will ſometimes crop the heads, when young and tender; kine do not ſeem to touch it. It is ſaid to yield a very pure vegetable alkali when burnt [a].

A variety ſometimes occurs, with few or no ſpines on the leaves, which are alſo not ſo deeply indented [b]. And the leaves are either green on both ſides, or whitiſh underneath [c].]

PROPAGATION AND CULTURE.

The Saw-worts are hardy perennial plants, and will thrive in the open air in England. The firſt is rarely admitted into gardens, but the other ſorts are frequently preſerved in the gardens of the curious. The 10th, 11th, and 14th ſorts, have large knobbed roots; theſe are propagated only by ſeeds, which ſeldom ripen in England, ſo that the ſeeds muſt be procured from abroad. Theſe ſhould be ſown on an eaſt-aſpected border, where the morning ſun only comes; for if the ſeeds are expoſed to the mid-day ſun, they ſeldom ſucceed well. Theſe ſeeds will often grow the firſt ſummer, if they are ſown early in the ſpring, but ſometimes they will remain in the ground a year before the plants appear; ſo that if they ſhould not come up the firſt ſeaſon, the ground ſhould not be diſturbed, and muſt be kept clean from weeds till the following ſpring, when, if the ſeeds were good, the plants will come up; when theſe appear they muſt be kept clean from weeds; and if they are too cloſe, ſome of the plants ſhould be carefully drawn out while they are young, and planted into another border of light loamy earth, four inches aſunder; in this place they may remain till autumn, when theſe, and alſo thoſe in the ſeed-beds, ſhould be carefully removed to the places where they are deſigned to remain; the following ſummer theſe plants will flower, and the roots will abide ſeveral years, if they are planted in a light loamy ſoil not over wet.

The other perennial ſorts may be propagated by parting of the roots; the beſt time for doing this is in autumn; when their ſtalks begin to decay; for when they are removed in the ſpring, if the ſeaſon ſhould prove dry, their roots will not be ſufficiently eſtabliſhed to flower well the ſame year. Theſe plants ſhould not be removed or parted oftener than every third year, if they are expected to grow ſtrong; nor ſhould they be parted into ſmall heads, for thoſe will make no figure the firſt year. As theſe plants grow tall, ſo they ſhould be planted in the middle of large borders, or with other tall plants; they may be planted in ſpaces between ſhrubs, or on the borders of woods, where they will have a good effect during their continuance in flower; and as they require no other culture than to dig the ground between them every ſpring, and keep them clean from weeds, ſo they are proper furniture for ſuch places.

Theſe ſorts are alſo propagated by ſeeds, when they can be obtained good; theſe may be ſown in the ſame way as the bulbous-rooted kinds, and when the plants come up, they muſt be treated in the ſame manner, only that theſe ſhould be allowed more room, for the fibres of their roots ſpread out on every ſide to a great diſtance; for which reaſon theſe plants ſhould not be planted in ſmall gardens, where they will overbear the neighbouring plants.

DESCRIPTIONS, &c.

1. This is an annual plant, riſing with an herbaceous four-cornered ſtalk about two feet high, ſending out a few ſhort ſide-branches. Leaves oppoſite and a little hairy. Flowers in looſe terminating ſpikes, ſmall, of a dirty white colour, ſhaped ſomewhat like thoſe of the Foxglove.

[Stem erect, round, hairy; with few branches, placed below. Leaves petioled, veined, having ſmall hairs ſcattered over them. Flowers axillary, ſolitary; on a very ſhort peduncle, at the baſe of which are two ſhort linear bractes, and within each a yellow perforated gland. Calyx gaping, almoſt equal. Corolla obſcurely five-lobed, blunt, the lower lobe more produced and rounded. Stamens four, two above the others, and between the latter the caſtrated rudiment of a fifth filament [d]. Capſule oblong, acuminate, rounded-quadrangular, with a groove on each ſide, four-celled, two-valved: partition double; one thicker, ſolid, from the dorſal groove of the valves; the other thinner, bilamellate, formed from the margins of the valves bent in. Seeds ovate-acuminate, compreſſed a little, ſmooth, whitiſh, marked on one ſide with a ſlender longitudinal ſtreak, faſtened along the central angle of the cells [e].

Native of the Eaſt Indies. Cultivated in 1731 by Mr. Miller. It flowers in july [f].]

It is frequently cultivated in the Levant, and alſo in Africa, as a pulſe; the ſeeds have been introduced in Carolina by the African negroes. An oil is extracted from the ſeeds, which will keep many years, and not acquire any rancid ſmell or taſte, but in two years become quite mild, ſo that when the warm taſte of the ſeed, which is in the oil when firſt drawn, is worn off, it is uſed as ſalad oil, and for all the purpoſes of ſweet oil.

The ſeeds are alſo uſed by the negroes for food: they parch them over the fire, then mix them with water, and ſtew other ingredients with them. A pudding is made with them, in the ſame manner as with Millet or Rice; called Benny or Bonny in Carolina.

[In Japan, where they have no butter, they uſe the oil for frying fiſh, and in dreſſing other diſhes; as a varniſh; and medicinally as a reſolvent and emollient [g]. In China and Cochinchina it is alſo uſed for the ſame purpoſes [h].

Browne ſays that the Seſamum plant is cultivated in Carolina with great ſucceſs, and it is computed there, that nine pounds of the ſeed yield upwards of two pounds of neat oil, which they find to grow more mellow and agreeable with age, and to continue without any rancid ſmell or taſte for many years.]

2. The ſecond ſort grows naturally in India, and is alſo an annual plant. The ſtalk riſes higher than that of the former: the lower leaves are cut into three parts: and theſe are the only differences between them.

[Theſe plants were introduced into Jamaica by the Jews, and are now cultivated in moſt parts of the iſland. They are called Vanglo or Oil-plant. The ſeeds are frequently uſed in broths by many of the Europeans, but the Jews make them chiefly into cakes. Many of the oriental nations look upon the ſeeds as a hearty wholeſome food, and expreſs an oil from them, not unlike, or inferior to, the oil of Almonds. A decoction of the leaves and buds is looked upon as a good reſolutive, and frequently ordered in inflammations of the eyes, where warm fomentations become requiſite [i]. It was cultivated by Mr. Miller in 1731 [k].]

β. This grows naturally in Africa, and is alſo an annual plant, with a taller and more branched ſtalk than either of the former. All the leaves are cut into three parts.

Mr. Miller raiſed two other ſpecies (or perhaps varieties) from ſeeds which were brought from Africa. They grew near four feet high; the leaves of one were much longer than any of the other, and thoſe towards the top were divided into three and ſometimes four parts. The ſeeds of this were black. The other had broader leaves, which were ſerrate. The flowers were large and of a pale blue colour, and the ſeeds were of a pale yellow colour. Being ſown late, no good ſeeds could be obtained from them.

[d] Linn. ſpec. [e] Gærtner. [f] Hort. kew. [g] Thunberg. [h] Loureiro. [i] Browne. [k] Hort. kew.

PROPAGATION AND CULTURE.

In England, theſe plants are preſerved in botanic gardens as curioſities. Their ſeeds muſt be ſown in the ſpring upon a hot-bed, and when the plants are come up, they muſt be tranſplanted into a freſh hot-bed to bring them forward. After they have acquired a tolerable degree of ſtrength, they ſhould be planted into pots filled with a rich, light, ſandy ſoil, and plunged into another hot-bed, managing them as has been directed for Amaranthuſes: for if theſe plants are not thus brought forward in the former part of the ſummer, they will not produce good ſeeds in this country; though after they have flowered, if the ſeaſon is favourable, they may be expoſed in a warm ſituation with other annual plants. When theſe plants have perfected their ſeeds they decay, and never continue longer than one ſeaſon.

DESCRIPTIONS, *&c.*

1. Native of the Cape of Good Hope. Found there by Thunberg.

2. Root perennial. Leaves pinnate, with the pinnas multifid, and the ſegments alternate: theſe alſo are cut alternately into linear flat ſegments turned outwards. Stem a foot high, round, before flowering-time decumbent, but about the ſeaſon of flowering almoſt upright, with one or two leaflets: petiole membranaceous, like a ſheath, oblong; whence a ſingle peduncle. The umbels nod before flowering as in Pimpinella Saxifraga, without any univerſal involucre: partial involucre linear, narrow, almoſt the length of the umbellet. Seeds oval, with three raiſed ſtreaks.—Native of the South of Europe [l].]

3. Stem erect, near two feet high, ſending out branches from the ſide. Leaves ſhort, divided into ſmall ſegments like Hog's-Fennel: at the foot-ſtalk of each a bellied membrane embracing it. Flowers white.

[Stem a foot high, round, even. Root-leaves ſhorter, like thoſe of Carrot, bipinnate, often cruciate at the rib, with the leaflets ſubtripartite. Stem-leaves with a petiolar ſheath entire: pinnate: leaflets ternate: pinnas three-parted, linear, ſharpiſh, ſomewhat remote, longer, channelled. Umbels with ſhort pedicels. Seeds pubeſcent [m].

It differs from *glaucum*, according to Villars, in having the leaves greener, more numerous, and narrower, the ſtems higher and more branched, and the ſeeds leſs aſh-coloured. The ſtem is from a foot to a foot and half in height, purpliſh, and terminating in two or three branches, which are a little divaricating. Root-leaves green, bipinnate, with the leaflets linear, winged, in threes, an inch long, and a third of a line wide, ſmooth above, decurrent without articulation at the baſe. Stem-leaves triangular, with the ſegments more lengthened out. Rays of the umbel eighteen or twenty; of the umbellet twenty to twenty-five, with an involucret of five or ſeven leaves, ſhorter than the rays, linear, and united at the baſe. Seeds ſtriated, often reddiſh at the end, a little aſh-coloured, ſomewhat larger than thoſe of glaucum.

Native of Italy and France.—Common on the dry hills of the latter, according to Moriſon. Ray found it on the hills and cliffs of the kingdom of Naples.—It was cultivated in the botanic garden at Oxford, in 1658 [n].

β. Root perennial. Stems patulous, round, ſtriated, ſmooth. Leaves all bipinnate, with the leaflets linear entire and ſubtrifid; on the upper ſtem-leaves longer.

[l] Linn. ſpec. [m] Idem. [n] Hort. kew.

Digitized by Google

In the lower ſtem-leaves a ſhort ſheath terminates in a long petiole. The upper petioles ſheathed almoſt embracing the ſtem are terminated by a compound ſeſſile leaf. Rays of the umbel from eight to twelve. Umbellets compact with from ſix to eight flowers, and an involucret of ſeveral awl-ſhaped leaves the length of the germs. The ſtyles and apex of the germ become red after the flower is paſt. According to the deſcription of *Seſeli Hippomarathrum* in Species plantarum, this reſembles that plant ſo much, that except in the form of the involucrets they appear to be the ſame [o].

4. Native of the Cape of Good Hope. Found there by Thunberg.]

5. Root perennial, running deep in the ground, and ſending out ſlender ſmooth ſtalks near two feet high. Leaves long and narrow, compoſed of ſeven or eight pairs of pinnas, with leaflets either ſingle or bifid; they have a membrane embracing the petiole, and are of a gray colour. The ſtalks are terminated by umbels of flowers, which are purple on their outſide and white within; [and therefore appear purple before they open, but when open white with purple anthers [p].

Stem about a foot high, ſtraight and little branched, terminated by an umbel, and one or two lateral branches beſides. Leaves glaucous: root-leaves bipinnate, with the leaflets in pairs or threes, with a nerve prominent on both ſides, jointed at their baſe, five or ſix lines in length, and half a line in breadth. Thoſe on the ſtem are ſmaller, with ſegments more lengthened out, and leſs compound. The umbel has only ten or twelve unequal rays; the umbellet twelve or fifteen, with an involucret of five leaflets ſhorter than the rays. Seeds ſmall, whitiſh, ſtriated, with little tubercles or hairs, viſible with a magnifier [q].

Native of France, Auſtria, Carniola, Sileſia, Piedmont.—Cultivated in 1759, by Mr. Miller [r].]

6. Root biennial. Leaves bipinnate, with the leaflets very narrow, and finely divided. Stems ſtrong, a foot and half high, with ſhining pinnate leaves, and terminated by pretty large umbels of whitiſh flowers.

[Native of the Pyrenean mountains. Cultivated in 1759, by Mr. Miller [s].

7. Stem ſtiff, a ſpan high and more, ſtriated. Leaves bipinnate, laciniate. Flowers whitiſh with a tinge of violet [t]. According to Haller and Gouan the involucrets are longer than the rays.

Leaves oblong, bipinnate, with linear leaflets, aſh-coloured, a little decuſſated like thoſe of *Carui*. Stems a foot high and more, ſtout, channelled, purpliſh, ſwelling a little under the joints, and branching at the end. Stem-leaves leſs compound, with their ſegments more lengthened out, but not ſo different as in ſome other ſpecies. The umbel has ſometimes an involucre of five linear leaves, and is compoſed of from ſixteen to twenty rays. Thoſe of the umbellet are numerous and cloſe. This has an involucre of ſeveral leaflets, the length of the rays or peduncles. Seeds ſmooth, ſtriated, oblong, purpliſh at the end. It is not properly annual, but dies, as many other umbellate plants do, after flowering and fruiting [u].

Native of France, Germany, Hungary, Auſtria, Switzerland and Piedmont.

8. Native of the Cape of Good Hope, where it was found by Thunberg.]

9. This is an annual plant. The leaves are like thoſe of Spignel, (Athamanta Meum) but much ſmaller, and have a very acrid biting taſte. The ſtalks riſe four inches high, and ſuſtain a ſmall umbel of flowers.

[It is a ſmall, very branching plant. The root-leaves much reſemble thoſe of Milfoil. Umbels many, with four or five divaricating rays in the circumference, and two or three ſmall ones in the diſk. Involucrets with two or three ſmall rays. Petals white, retuſe. Anthers violet. Seeds ſtriated.

Native of Portugal and Italy [x]. Cultivated by Mr. Miller in 1759. It flowers in june and july [y].]

[o] Retzius. [p] Linn. ſpec. [q] Villars. [r] Hort. kew. [s] Idem. [t] Linn. ſpec. [u] Villars. [x] Linn. ſpec. [y] Hort. kew.

10. This has a thick woody root, from which come out ſtiff ſtalks near four feet high, which are crooked at their joints, and have narrow leaves coming out in bunches. The ſtalks divide into ſlender branches, which have ſmall umbels of flowers coming out of their ſides, and are terminated by larger. The flowers are ſmall and yellow.

Stem rigid, as it were woody. Partial leaflets not two only oppoſite, but commonly four, the inner ones ſmaller, whence they are bundled [a].

Cultivated in 1656 by Mr. John Tradeſcant, jun. Biennial [b].

11. Native of the South of Europe.

12. Leaves bipinnate; the firſt trifid and linear. Stem ruſhy, glaucous, as is the reſt of the plant. The uppermoſt leaves conſiſt of a ſheath only. Involucrets of one leaf, like a baſin, notched about the edge, or of leaflets united into one; in which this differs from all other umbellate plants. Germs ſeſſile. Corollas white, often tinged with purple [c]. According to Scopoli and Gouan, the ſynonym from Caſpar Bauhin belongs to Pimpinella glauca [d].

Native of Auſtria, Carniola, Sileſia, Germany.—Cultivated in 1656 by Mr. John Tradeſcant, jun. [e]

13. Stem a foot high, round, ſtriated. Root-leaves doubly pinnate, looſe, little divaricating: leaflets pinnate, longitudinally gaſhed, acuminate, wedge-ſhaped. Upon the ſtem there is often a ſingle leaf, from the axil of which iſſues a branch: radical petioles ſimple; ſtem-petiole wide-membranaceous. Univerſal umbel naked, oblong, with about eight rays or peduncles: partial cluſtered, very ſhort, uniform; with a many-leaved, briſtle-ſhaped involucret, longer than the umbellets. The appearance of this ſpecies is different from the others of this genus.

Native of the Pyrenees [f].

14. Plant a foot high. Stem branched, round, ſlender. Leaves ſmall, doubly-ternate, linear, ſeldom lobed. Umbels naked, commonly with ſix peduncles or rays: umbellets involucred, with from ſix to eight florets; involucrets briſtle-ſhaped.

Native of Germany, and the borders of the Lake of Geneva [g].

15. Stem a foot and half high, the thickneſs of a pigeon's quill, ſubdichotomous, with the branches divaricating; the uppermoſt very narrow. Leaves ſuperdecompound; the upper ones only ternate. Leaflets linear, the thickneſs of a horſe-hair, an inch long, round. Umbels trifid. Umbellets cluſtered, with about eight florets, which are white. Involucrets extremely minute. Seeds tubercled [h].

This plant is eaſily diſtinguiſhed by its cylindrical leaflets, coming out in threes, and from one to two inches in length. The ſtem riſes from one to two feet in height, and has ſpreading branches. Umbels ſmall. Involucret of ſeveral leaflets. Seeds rugged, ſmall, notchletted, tranſverſely wrinkled, crowned with the perianth, like the Oenanthes. It is biennial. The membranous ſheath of the leaves ſurrounds the ſtem, and is ſeparated from the leaflets by a depreſſion, and by the direction of the leaf, which from perpendicular, as it was when applied to the ſtem by the ſheath, takes a horizontal poſition at that place [i].

Native of France, Auſtria and Sileſia. Crantz could not find it in Auſtria.]

PROPAGATION AND CULTURE.

Sow the ſeeds in autumn, and they will riſe the following ſpring; whereas when they are ſown in the ſpring, they frequently lie in the ground till the next year before they grow. Drill them eighteen inches aſunder, in a bed of freſh earth, where they are deſigned to remain; thin the plants to the diſtance of ſix inches; keep them clear from weeds; and in the ſecond ſeaſon they will produce ſeeds. The perennial ſorts ſhould have the ground gently dug every ſpring between the rows, taking care not to injure their roots with the ſpade. Theſe plants love a moiſt ſoil; and

Halimus indicus. *Rumph. amb.* 5. 165. *t.* 72. *f.* 1.

DESCRIPTION, *&c.*

Root perennial. Stems herbaceous, four or five inches long, decumbent, ſubdivided, round, ſucculent. Leaves wedge-ſhaped, on very ſhort petioles, oppoſite, obtuſe, fleſhy, thick, ſmooth, bright green. Petioles ſheathing, embracing, with membranaceous edges. Peduncles ſolitary, axillary, ſhorter than the leaves. Flowers green on the outſide, white and blood-red within. Calyx corolline. Anthers ſmall, blood-red. Germ acuminate. Styles three, ſometimes but ſeldom four. Seeds black [i].

Native of the Weſt Indies. Very common in Jamaica, in all the low lands about the Ferry, growing in thick beds, on every ſpot of ground that riſes above the level of the water. It is very ſucculent, and full of a neutral-alcaleſcent ſalt, which may be eaſily extracted, and would probably anſwer all the purpoſes for which the ſalts of the Kali are now uſed [k].

Leaves in fours equal, ſtem ſhrubby.

DESCRIPTIONS, *&c.*

1. Root annual, with many reddiſh-brown fibres. The whole plant branched, diffuſed, rough and hairy, from four to ſeven inches high. Leaves five or ſix in a whorl, ovate, acuminate, rough along the edges and keel; the lower ones broader and fewer in a whorl. Umbel terminating, ſeſſile, the uppermoſt whorl of eight leaves ſerving it for an involucre. Calyx ſuperior, two-leaved; leaflets three-toothed, permanent, crowning the fruit. Corolla with a long ſlender tube; the border bright purple [a]. Seeds ovate, bay, having very minute briſtles ſcattered over them, and preſſed cloſe to them, convex on one ſide, on the other having a longitudinal cleft widening inwards. It differs from Aſperula only in the crown upon the ſeed [b].

Native of many parts of Europe, among corn and on fallows; flowering during the greateſt part of the ſummer.

2. Root annual. Stems decumbent. Leaves ovate-lanceolate, ſix in the lower, four in the middle whorls, two only together at top. Flowers in pairs on their proper peduncles, pale, flat. Fruits oblong, hiſpid. Seeds bowed a little, with little or no crown.

Native of Italy. Found alſo at Conſtantinople, on walls.

3. This is a toroſe, irregular, rugged ſhrub, with the branches bluntly four-cornered. Leaves in fours, narrow-lanceolate, quite entire, ſmooth, rolled back at the edge, a little longer than the internodes of the branches, ſeparated by very ſhort, awl-ſhaped ſtipules. Flowers oppoſite, ſeſſile, axillary. Calyx four-leaved, growing upon the germ, with lanceolate leaflets permanent. Corolla funnel-form, four-cleft, white, length of the germ. Anthers four oblong. Pericarp two-grained. It is one of the very few plants which the iſland of Aſcenſion affords; and was found there by Oſbeck [c].

According to Swartz this ſpecies is between a *Spermacoce* and a *Diodia*; and leſs allied to the genus *Sherardia*.

SHERARDIA. See *Galenia* and *Verbena*.
SHOT, INDIAN. See *Canna*.
SIAMIN. See *Pentapetes*.]

Stem upright, leaves linear-filiform three-parted.

DESCRIPTIONS, *&c.*

1. Root woody, branched, black on the outſide. Stems very ſhort, leafy. Leaves on long petioles, ternate: leafleſs inverſely wedge-ſhaped, hairy, three-toothed at the end. Stipules two, faſtened to the petiole. Peduncles corymbed. Flowers ſmall, yellow. Calyx hairy, permanent, with the alternate ſegments larger. Petals obovate, entire. Stamens very ſhort. Styles five, ſometimes ten. Seeds ovate gibbous [d]: according to Gærtner, five, ſmall, ſubglobular, acuminate, ſmooth, of a yellow-bay colour.—When cultivated, the ſtamens are often ſeven or more; the germs ten; and ten ſeeds, fixed to a dry hairy receptacle [e]. Hence Miller has made a ſecond ſpecies, which he names *octopetala*, and is no more than a variety. Dr. Smith is of opinion, that Plukenet's figure (*t.* 212. *f.* 3.) which Linneus refers to this, belongs rather to *Potentilla ſubacaulis*.

Native of the mountains of Lapland, Switzerland, Scotland and Siberia. On the north ſide of Ben Lomond, three fourths up the mountains, plentifully. On Ben Mor, ſparingly. Flowering in july.

2. The leaves are very finely jagged, and the flowers fleſh-coloured.—Native of Siberia [f].

3. Leaves linear, three-cuſped. Calyxes cylindrical. Corollas purple [g]. Stem an inch high or more, almoſt naked, having only one flower, or elſe terminated by a corymb of from three to five flowers [h].]

PROPAGATION AND CULTURE.

1. Growing on moiſt ground in high mountains, it is with difficulty preſerved in gardens, and rarely produces ſeeds there; the plants therefore muſt be procured from the places where they grow naturally, and if they are planted in a moiſt ſoil and ſhady ſituation, they will thrive tolerably well and produce flowers.

Leaves kidney-form-ſubpeltate crenate.

DESCRIPTION, *&c.*

1. [Root fibrous, perennial. Stems proſtrate, creeping, branched, very long, ſlender and delicate, interwoven, leafy, hairy. Leaves alternate, on footſtalks, horizontal, with ſhallow diſtant notches, hairy. Peduncles axillary, ſolitary, ſhort, one-flowered, hairy. Calyx hiſpid. Corolla pale yellow, with a purpliſh tinge in the three upper ſegments. Stamens very ſhort. Stigma peltate[x]. Capſule ſmall, cordate-rounded, with a groove on each ſide, compreſſed like a lens, two-celled, two-valved: partition ſimple, very narrow, contrary to the valves. Receptacle ſubglobular, ſpongy, tubercled, faſtened on each ſide to the middle of the partition. Seeds few, about ſix in each cell, ſmall ovate, plano-convex or ſubangular, brown[y].

This curious and moſt diſtinct genus was named, as was ſaid above, in honour of Dr. Humphrey Sibthorp, ſucceſſor to Dillenius in the Botanic chair at Oxford. His ſon, the late Profeſſor John Sibthorp, has richly earned his inheritance of the honour, by his indefatigable zeal in the purſuit of the ſame ſcience, to which indeed he fell a ſacrifice. His knowledge of the plants of his own country is diſplayed in his Flora Oxonienſis, publiſhed not long before his death. The arrangement of his Grecian treaſures is intruſted to Dr. Smith[z].

Native of Portugal, and England, in ſhady places and about ſprings; in Devonſhire and Cornwall, plentiful, and about Longſledale in Weſtmoreland. It flowers in july and auguſt, or from june to ſeptember.]

PROPAGATION AND CULTURE.

Planted or ſown in pots, placed in the ſhade and kept moiſt, it will thrive very well in gardens.

Lin. ſpec. 1439. *Reich.* 4. 209. *hort. cliff.* 452. *upſ.* 291. *Berg. cap.* 352. *Sabb. hort.* 1. *t.* 60. *Dill. elth.* 58. *t.* 51. *f.* 59. (Bryonioides.) *Pluk. phyt. t.* 26. *f.* 4. (Cucumis.)

β. Cucumis canadenſis monoſpermos, fructu echinato. *Herm. par.* 108. *t.* 133.

Leaves angular.

2. Sicyos laciniata. *Jagged-leaved Sicyos.*

Lin. ſpec. 1439. *Reich.* 4. 210. *Plum. ſpec.* 3. *ic.* 243. (Sicyoides.)

Leaves jagged.

[3. Sicyos Garcini. *Garcin's Sicyos.*

Lin. ſyſt. 870. *Reich.* 4. 210. *mant.* 297. *Burm. ind.* 311. *t.* 57. *f.* 3.

Leaves five-parted eroſe-toothed, fruits ciliate.]

DESCRIPTIONS, *&c.*

1. This is an annual plant, which riſes with two large ſeed-leaves like thoſe of the Cucumber; the ſtalk is trailing, and has tendrils, by which it faſtens itſelf to neighbouring plants, and will riſe fifteen or ſixteen feet high, dividing into many branches, with angular leaves on them like thoſe of the Cucumber. The flowers come out upon long peduncles from the ſide of the branches in cluſters; the females are ſmall, of a pale ſulphur colour, and appear in june and july; they are ſucceeded by prickly oval fruit, ripening in autumn. [The fruit is an inferior fleſhy berry, becoming juiceleſs, coriaceous and membranaceous, ovate-acuminate, compreſſed a little, covered all over with a rigid curling cotton, and ſlender yellowiſh pungent ſpines; one-celled. Seed ovate, compreſſed a little, ſmooth, of a ruſty brown colour, with four white calluſes at the navel[a].

Native of North America. Cultivated in 1732 by James Sherard, M. D.[b]]

2. This is alſo an annual plant, with trailing ſtalks like the former; but the leaves are cut into ſeveral ſegments. The flowers are larger and of a deeper colour. The fruit is not quite ſo large, nor ſo cloſely armed with prickly hairs.—Native of the Weſt Indies.

[3. Leaves cordate, five-parted with the ſinuſes obtuſe: ſegments ſinuate with mucronate teeth. Fruit ſeſſile, ſolitary, ciliate, preſſed to the ſtem.—Native of Ceylon[c].]

PROPAGATION AND CULTURE.

1. If the ſeeds be permitted to ſcatter, the plants will come up in the ſpring better than when ſown by hand, and require no other care but to keep them clean from weeds. Theſe plants ramble, and take up too much room in ſmall gardens; they ſhould therefore be allowed a place near a hedge, upon which they may climb: they do not bear tranſplanting well, unleſs when they firſt come up.

2. Sow the ſeeds upon a hot-bed in the ſpring, and treat the plants in the ſame way as Cucumbers and Melons, keeping them under frames. They

require more room, ſo that a plant or two will be enough for curioſity.

[SICYOS. See *Ciſſus* and *Elaterium*.]

SIDA. (Σιδη *of Theophraſtus.*)

Lin. gen. n. 837. *Reich. n.* 902. *Schreb. n.* 1129. *Cavan. diſſ.* 1. 6. *L'Herit. ſtirp. faſc.* 5. *Gærtn. fruct. t.* 134. *Juſſ.* 273. Malvinda. *Dill. eltb.* 171. 172. Abutilon. *Dill. eltb.* 2. 5. 6. *Tournef. t.* 25. Anoda. *Cavan. diſſ.* 1. Napæa. *Clayt.* & *ed. prior.*

Claſſ. 16. 6. Monadelphia Polyandria.

Nat. order of *Columniferæ*. *Malvaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leaſed, angular, half-five-cleft, permanent.

COR. *Petals* five, wider above, emarginate, faſtened below to the tube of ſtamens.

STAM. *Filaments* very many, united below into a tube, in the apex of the tube divided. *Anthers* roundiſh.

PIST. *Germ* orbicular. *Styles* five or more; or elſe one many-cleft. *Stigmas* headed.

PER. *Capſule* roundiſh-angular, compoſed of five or more cells, (correſponding with the number of the ſtyles or ſtigmas,) two-valved, awnleſs, acuminate or horned, opening above, or cloſe, and finally ſeparating.

SEEDS ſolitary, two three, or five, roundiſh, moſtly acuminate, convex on one ſide, angular on the other, faſtened to the interior future.

OBS. Malvinda, *Dill. has five cells with one ſeed in each.*

Abutilon, *Dill. & Tourn. has ſeveral cells, and commonly ſeveral ſeeds in each.*

Anoda, *Cavan. has ſeveral united cells with one ſeed in each.*

Napæa, *Linn. is dioecous, with ſeveral cells not opening.*

Sida periplocifolia, *Linn. has five ſuperior two-valved cells, and as many inferior alternate not opening.*

SPECIES.

S. carpinifolia. *Mill. dict. n.* 2.

Stewartia corchoroides. *Forſk. deſcr.* 126.

Leaves ovate-lanceolate obſoletely cordate toothed, peduncles ſubſolitary axillary, axils ſomewhat ſpiny, ſtipules briſtle-ſhaped longer than the peduncle, capſules two-beaked.

[7. Sida fruteſcens. *Shrubby Sida.*

Lin. ſpec. ed. Willd. 3. 736. *Cavan. diſſ.* 1. 12. *t.* 10. *f.* 1.

Leaves ovate-oblong, ſerrate, peduncles one-flowered axillary, capſules two-beaked.

8. Sida carpinifolia. *Hornbeam-leaved Sida.*

Lin. ſyſt. 621. *ed. Willd.* 3. 737. *ſuppl.* 307. *Jacqu. ic. rar.* 1. *t.* 135. *collect.* 1. 38. *Cavan. diſſ.* 5. 274. *t.* 134. *f.* 1.

S. planicaulis. *Cavan. diſſ.* 1. 24. *t.* 3. *f.* 11.

Leaves ovate-oblong ſubduplicate ſerrate, peduncles axillary four-flowered or thereabouts, capſules two-beaked.

9. Sida jamaicenſis. *Jamaica Sida.*

Lin. ſpec. 962. *ſyſt.* 621. *Reich.* 3. 336. *Willd.* 3. 737. *amoen.* 5. 401. *Swartz obſ.* 258. *Cavan. diſſ.* 1. 17. *t.* 2. *f.* 5. *Brown. jam.* 280. 5.

Leaves ovate ſerrate tomentoſe, flowers axillary ſubpeduncled, capſules in fives two-horned.

10. Sida orientalis. *Oriental Sida.*

Lin. ſpec. ed. Willd. 3. 737. *Cavan. diſſ.* 1. 21. *t.* 12. *f.* 1.

Leaves ovate acuminate toothed ſmooth, peduncles one-flowered axillary, capſules awnleſs.

11. Sida glomerata. *Globe-flowered Sida.*

Lin. ſpec. ed. Willd. 3. 738. *Cavan. diſſ.* 1. 18. *t.* 2. *f.* 6.

Leaves ovate-lanceolate ſerrate, flowers about five together axillary ſubſeſſile, capſules two-horned.

12. Sida maculata. *Spotted-flowered Sida.*

Lin. ſpec. ed. Willd. 3. 738. *Cavan. diſſ.* 1. 20. *t.* 3. *f.* 7.

Leaves ovate obtuſe ſerrate tomentoſe, peduncles axillary racemed at the top of the ſtem, capſules two-horned.

13. Sida ſuberoſa. *Corky Sida.*

Lin. ſpec. ed. Willd. 3. 738. *L'Herit. ſtirp.* 1. 113. *t.* 54.

Leaves ovate toothed hirſute, peduncles axillary one-flowered twice as long as the petiole, capſules two-horned, ſtem corky at the baſe.

14. Sida capenſis. *Cape Sida.*

Lin. ſpec. ed. Willd. 3. 738. *Cavan. diſſ.* 1. 23. *t.* 12. *f.* 3. & *diſſ.* 2. 49. *Pluk. phyt. t.* 240. *f.* 5.

Leaves ovate-lanceolate toothed, peduncles ſolitary, ſtipules linear ciliate longer than the petiole.

15. Sida microphylla. *Small-leaved Sida.*

Lin. ſpec. ed. Willd. 3. 739. *Cavan. diſſ.* 1. 22. *t.* 12. *f.* 2.

Leaves elliptic toothed, peduncles ſolitary longer than the petiole, capſules two-horned.

16. Sida micans. *Glittering Sida.*

Lin. ſpec. ed. Willd. 3. 739. *Cavan. diſſ.* 1. 19. *t.* 3. *f.* 1.

Leaves ovate obtuſe ſerrate tomentoſe ſhining, peduncles ſolitary much longer than the petiole, capſules two-horned.

17. Sida puſilla. *Dwarf Sida.*

Lin. ſpec. ed. Willd. 3. 739. *Cavan. diſſ.* 1. 6. *t.* 1. *f.* 4. & *diſſ.* 5. *t.* 127. *f.* 1.

Leaves roundiſh-elliptic toothed ſmooth, peduncles longer than the petiole ſolitary, capſules awnleſs, ſtem proſtrate.

** *With wedge-ſhaped leaves.*

18. Sida rhombifolia. *Rhomb-leaved Sida.*

Lin. ſpec. 961. *ſyſt.* 621. *Reich.* 3. 334. *Willd.* 3. 740. *vir. cliff.* 68. *hort. cliff.* 346. *upſ.* 199. *fl. zeyl. n.* 252. *Gron. virg.* 101. *Murr. prodr.* 168. *Kniph. cent.* 8. *n.* 85. *Cavan. diſſ.* 1. 23. *t.* 3. *f.* 12. & *diſſ.* 2. 48. *Swartz obſ.* 257. *Forſt. prodr. n.* 256. *Sloan. jam.* 1. 217. (Malva.) *Dill. eltb.* 216. *t.* 172. *f.* 212. (Malvinda.). *Bocc. ſic.* 11. *t.* 2.

Leaves oblong lanceolate toothed wedge-form at the baſe quite entire, peduncles much longer than the petioles, capſules two-horned.

DESCRIPTIONS, *&c.*

This genus, which contained only twenty-ſeven ſpecies in the 14th edition of the Syſtema Vegetabilium by Murray, is thus enlarged chiefly by the labours of Cavanilles, whoſe ſpecies have been adopted by Willdenow, with new ſpecific characters. It contains either ſhrubs or herbs, with a few trees; the herbaceous ſpecies are moſtly annual or biennial. The flowers are axillary or terminating, with the pedicels as it were jointed under the calyx, according to the obſervation of Cavanilles; who alſo remarks, that the petals in the ſpecies with five or ten capſules having one ſeed in each, are commonly produced on one ſide obliquely and ſomewhat in form of a ſickle. The capſules in *S. veſicaria* are five-ſeeded.—Cavanilles ſeparates three ſpecies, (89, 90, 91.) which he names *Anoda*, from the pedicels not being jointed: they are herbaceous, with the flowers ſolitary and axillary, but differ principally in having a ſimple fruit.—The ſame author unites *Napæa* with Sida. The two ſpecies of that genus are tall herbs, and one of them is dioecous: the petals in theſe are not oblique, nor are the pedicels jointed; the calyx alſo is wider at the baſe[d]. Theſe plants are moſtly natives of the Eaſt and Weſt Indies, not one properly of Europe, though *S. Abutilon* has eſtabliſhed itſelf in ſome of the ſouthern parts.

1. The leaves of this are rough with hairs, and it has five capſules.—Native of Peru and the iſland of Cayenne[e].]

2. This riſes with a ſlender woody ſtalk about two feet high, ſending out many erect branches. Leaves an inch and half long, and a third of an inch broad in the middle, ending in acute points, and placed on pretty long ſlender foot-ſtalks. The flowers come out ſingly from the axils, are ſmall, and of a pale yellow colour. [According to Willdenow, there are ſometimes two flowers from an axil, and the capſules are five.—Retzius deſcribes his *ulmifolia* as annual, with the leaves very ſoft beneath, though the nap is ſcarcely obſervable; the ſtipules briſtle-ſhaped; no ſpines; peduncles many, axillary, one-flowered.

According to L'Heritier it is ſcarcely ſuffruteſcent, and continues only a few years; the branches, which are few, are wand-like, round and ſubpubeſcent; below each leaf is a very ſhort reflexed triple ſpine, the ſide ones very ſmall; leaves alternate, ſcarcely tomentoſe beneath but paler, on round ſubpubeſcent petioles thickiſh at the top and only one third of the length of the leaves; ſtipules awl-ſhaped, erect, deciduous; flowers one, two or three from an axil, peduncled, erect, yellow, half an inch in diameter; peduncles jointed in the middle, ſcarcely pubeſcent, ſhorter than the petiole. Capſules five, round on one ſide, angular on the other, with two villoſe horns. Seeds ſolitary, gibbous on one ſide, angular on the other, brown.—*S. ſpinoſa*, *truncata*, and *rhombifolia* are very nearly allied to this in the herb, flowers and ſpines. *S. anguſtifolia* differs indeed only by its linear leaves.

Native of Braſil and the iſland of Bourbon.

3. Like the preceding, but with the flowers ſolitary in the axils, and the ſtipules lanceolate not ſetaceous. Native of Java.[f]

4. Capſules nine or ten two-beaked. Native of the Canary Iſlands. It is the *alba* of Cavanilles, but not of Linneus.

5. Stipules linear, nerved, ciliate, one of them commonly filiform. Capſules five to nine[g].—Stem upright, branched, nappy here and there; leaves acuminate, acutely ſerrate, naked, on ſhort petioles; ſtipules longer than the petiole, and peduncles a little longer

[d] Juſſieu. [e] Willdenow. [f] Idem.

Digitized by Google

than the ſtipules; flowers ſmall; capſules acuminate-awned.

Native of the iſlands of Ceylon and Mauritius; Retzius's ſpecimen was ſent by Koenig. Annual.]

6. Stems hairy, branching, near three feet high: the branches come out from the bottom almoſt to the top, and form a pyramidal buſh. Leaves lanceolate, deeply ſerrate, on ſhort petioles. Flowers axillary, ſolitary towards the bottom of the ſtem, but above in cluſters, of a pale ſulphur colour.

[Native of the Eaſt Indies, Arabia Felix, Senegal, Jamaica and Guiana. Annual. Introduced, according to the Kew catalogue, in 1771, by Monſ. Richard. Probably Mr. Aiton conſidered the Eaſt Indian plant as different from the Weſt Indian and Mr. Miller's *carpinifolia*.

7. This has five capſules and is ſhrubby. It is not known where it is a native.

8. Branches ſpreading in two rows and hairy. Leaves on ſhort petioles, in two rows, ovate-lanceolate ſerrate, the ſerratures terminated by a hair or rigid briſtle, veined, ſmooth. Stipules awl-ſhaped, longer than the petiole, erect, converging. Peduncles axillary, ſeldom ſolitary, umbelled, length of the petiole which is hairy. Calyx ſmooth. Corolla yellow. Capſules eight[z], not awnleſs as Cavanilles has affirmed. Cultivated in the iſland of Madeira.

9. Stem ſuffruteſcent, a foot high, branched, round, hiſpid. Leaves petioled, alternate, ſmall, ſcarcely acuminate, nerved, ſoftiſh: petioles many times ſhorter than the leaves: leaves next the petiole ſlightly emarginate. Stipules oppoſite, at the baſe of the petioles, briſtle-ſhaped. Flowers on very ſhort peduncles, from one to three, ſmall, yellow. Beaks of the capſules very ſhort[h].

Very common in all parts of Jamaica. The leaves and tender buds contain a great quantity of mucilage, and lather like ſoap with water: they are frequently uſed in ſhaving-waſhes by ſuch as cannot conveniently bear the ſmell or acrimony of ſoap. The leaves are purgative. It is known by the name of Broom-weed in Jamaica[i].] Mr. Miller ſays, that he has received three or four ſpecies by this name, and has been informed that the inhabitants cut theſe plants as we do Heath, to make beſoms for ſweeping.

[10. Capſules nine or ten. Native of the Eaſt Indies[l].

11. Stem ſimple, a foot high, tomentoſe. Leaves tomentoſe. Stipules lanceolate erect. Calyxes ciliate. Corolla yellow[k]. Capſules five. Cavanilles has a variety with naked capſules, which may perhaps be a diſtinct ſpecies[l].

12. Corolla middle-ſized yellow with five red ſpots at the baſe. Capſules nine. Native of the Weſt Indies.

13. Capſules nine.—S. braſienſis of Cavanilles, *diſſ.* 1. 37. & *diſſ.* 2. 34. *f.* 1. is very nearly allied to this, yet ſeems to be different; it is however a dubious plant, the flowers and capſules of which are unknown. Native of Hiſpaniola.

14. Capſules ten, ſuppoſed to be a native of the Cape of Good Hope, though Plukenet entitles it *Althæa maderaſpatana*.

15. Capſules ſeven. Native of the Eaſt Indies.

16. Native of the Weſt Indies.

17. Capſules five. Native of the iſland of Mahe.

18. Native of the Eaſt Indies and Jamaica[m]. Cultivated in the Eltham garden in 1732.

19. Native of Senegal.

20. Capſules nine. Native of Tranquebar, Amboina, the Philippines, and the iſland of Mauritius. Annual. Dillenius regards it as a variety of the next ſpecies, but it ſeems to be diſtinct.]

21. Stem ſlender, woody, more than two feet high, ſending out ſeveral ſlender branches. Leaves on long foot-ſtalks, a little hairy on their under ſide. Flowers ſingle, or two or three together, upon ſlender peduncles, of a pale copper colour. [Capſules ſix or ſeven. Annual.—Native of the Eaſt Indies[n] and Cochinchina. Cultivated in 1732, by James Sherard, M.D.[o]

22. Stems many, trailing, dividing into ſlender branches, covered with a light-brown bark. Leaves ſmall, hairy on their under ſide, on ſhort foot-ſtalks. Flowers in ſmall cluſters, ſitting cloſe at the end of the branches, ſmall and bright ſcarlet. The capſules have two ſtiff briſtly teeth.

[Stems five or ſix inches long, fruteſcent, filiform, ſtrict, rugged; with diverging branches. Leaves terminating, in cluſters, oblong, retuſe, ſerrate towards the top. Stipules the length of the petioles. Flowers blood-red. Capſules five, depreſſed, muricate[p], awnleſs, according to Willdenow. Native of Jamaica and St. Domingo.

Browne ſays, that this little creeping plant is very common in the low lands of Jamaica, and ſeldom runs above ſeven or eight inches in length; that the flowers grow ſingle, each of the pedicels being generally adorned with one leaf and three ciliated ſtipules, which compoſe the outward cup: but that thoſe towards the top of the plant are very ſhort, ſo that the flowers appear as if they were diſpoſed in ſmall heaps at the axils of the leaves.

23. Root annual. Stem from two to four feet high, erect, ſimple, round, pubeſcent, ſometimes divided towards the top into ſpreading branches. Leaves petioled, alternate, ſmooth, ſomewhat wrinkled, hoary beneath. Panicle terminating, half the length of the ſtem, erect, almoſt ſimple, ſpreading. Peduncles ſimply ſubdivided, alternate, filiform, the laſt one-flowered. Flowers pale, ſometimes light purple. Capſules five, ovate, acuminate[q], or terminated by a ſingle awn, three-ſeeded. Native of the Weſt Indies and Ceylon[r]. Cultivated by Sherard at Eltham in 1732.

24. This is a lofty tree. Capſules five three-ſeeded. Native of Peru.

25. Capſules five three-ſeeded acute. Native of Hiſpaniola.

26. Leaves obſcurely crenate. Capſules five, ſix, or ſeven, three-ſeeded. Native of Peru and St. Domingo[s].

L'Heritier remarks, that in *S. bernandioides* the peduncles are more elongated than in moſt of the ſpecies; that the leaves have one lobe at the baſe ſo placed upon the other, as to be in a manner peltate, and to bear a tolerable reſemblance to thoſe of *Hernandia*; that the fruit is abſolutely the ſame as in *periplocifolia* and *nudiflora*; and that it is diſtinguiſhed from the former chiefly by the leaves being cordate-rounded, whereas in that they are cordate-lanceolate. The ſeeds were ſent from Hiſpaniola by Julien Franc. Duchemin de Leſtang: the plants flowered in the Paris garden in 1783, perfected their ſeeds, and then died in the winter.

The *nudiflora* is a ſhrub, three fathoms in height, and ſomewhat tomentoſe. It has the name from the panicles being naked, and not leafy as in *paniculata*, *bernandioides* and *periplocifolia*. Dombey found it in Huanuco a province of Peru, and ſent the ſeeds to the Paris garden, where it has flowered every year, but has not perfected ſeeds. The flowers are yellow, and an inch in diameter[t].

27. This is a ſhrub three feet in height, with ſubtomentoſe branches, having each of the three ſides hollowed out with a blunt groove. Leaves cordate without angles, very ſoft, obſcurely tomentoſe, bluntly ſerrate, acuminate. Peduncles axillary, one-flowered. Corolla yellow purple at the baſe. Stamens yellow. Style five-cleft[u]. Capſules five, three-ſeeded[v]. Gærtner deſcribes the capſule as ovate-oblong, flatted a little at the top, five-horned, rounded-five-cornered, five-celled, five-valved: partitions correſponding with the external groove, and inſerted into the middle of the valves, which after opening are two-horned at the top. Seeds about three in each cell, kidney-form-globular, blackiſh, marbled with aſh-coloured ſpots as if froſted, faſtened to the central margin of the partitions.

Native

Native of the Weſt Indies. Introduced in 1775, by Joſeph Nicholas de Jacquin, M. D.[z]

28. In habit this reſembles the *bernandioides*. Leaves three inches long, deeply cordate, with the lobes imbricate, and very long-pointed at the end. Petioles almoſt the length of the leaves. Peduncles ſolitary, three or four times ſhorter than the petioles. Capſules five, with one ſeed in each[y].

It differs from the *bernandioides* in having one-ſeeded capſules, peduncles ſhorter, without bractes, and one-flowered, (not having the rudiment of a ſecond flower, as that has,) and the herb hirſute and ſomewhat clammy, not villoſe-tomentoſe.

Native of Hiſpaniola, whence ſeeds of it were ſent to the Paris garden in 1781 and 1782 by Joſ. Nic. Thiery de Menonville. It flowered but did not bear fruit[x].

29. Capſules ſeven or eight, very hard, three-ſeeded. Native of St. Domingo[a].

30. This is ſufficiently diſtinguiſhed by the lateral filaments being gradual, as in *Hibiſcus*, not terminating and pencil-form, as in the other ſpecies; and the corolla abſolutely reflexed. Flowers drooping, blood-red with a duſky ſpot at the baſe of each petal[b]. Capſules twelve, three-ſeeded, according to Willdenow. Native of Peru.

31. Root annual. Stem branched, procumbent, round, hairy. Leaves hairy above, rugged beneath, on long hairy petioles. Stipules filiform, a little recurved. Peduncles ſolitary, very rarely two together, one-flowered, axillary. Flowers ſmall, yellow. Arils five, membranaceous, angular, perforated at the top, one-ſeeded[c]. According to Willdenow, it has five one-ſeeded capſules.

Its habit is that of the five-ſeeded Sidas, but the joints are unarmed, and the capſules have no horns or beaks. It is ſingular in having incomplete arils external only, not incarcerated or winged as in *S. pteroſperma*[d].

Native of the Eaſt Indies. Koenig ſent the ſeeds from Tranquebar. Commerſon alſo found it on the iſland of Mauritius.

Cavanilles has two other ſpecies, which Willdenow conſiders as varieties of this.

32. Stem proſtrate but not rooting. Capſules five, awnleſs or two-awned. Native of Peru, eſpecially in ſhady places about Lima[e].

33. Diſtinct from the other ſpecies to which it is allied by its awned-acuminate calyxes, and five cohering capſules ſlightly two-toothed at the ſide, obtuſe and two-valved. Native of St. Domingo.

34. Capſules five, with long hooked beaks ſtanding far out. Native of the iſland of St. Domingo[f].

Miller has a ſpecies under this name. *Ulmifolia* of Retzius is Miller's *anguſtifolia*. See *n.* 2.

35. Fruit within the calyx. Capſules nine, with long beaks in bundles. Native of Braſil.

36. Capſules about thirteen, three ſeeded, two-beaked when open: beaks ciliate. Seeds very ſmall[g].

37. Plant from two to four feet high, ſpreading. Leaves ſmall, hirſute. Flowers yellow. The whole plant is clammy, and ſmells very ſtrong[h].

Browne remarks, that this little ſhrubby plant ſeldom riſes above four or five feet in height; that the trunk is pretty woody, and covered with a whitiſh bark; the leaves and ſmaller branches a little villoſe; and that the ſeed-veſſels are few, flatted at the top, and compoſed of many cells.

Native of Jamaica, and according to Loureiro, of Cochinchina.

38. This differs from the preceding in the leaves not being acuminate or hairy, but ſoft with a very fine nap, much larger and groſsly toothed; the peduncles ſhorter than the petiole, and ſeven capſules ſqueezed into a ball[k].

According to Willdenow, this, and not the preceding, is the *viſcoſa* of L'Heritier; who remarks, that it has the leaves and habit of the *occidentalis* and *nutans*, but is eaſily diſtinguiſhed by its clammy ſtems and branches: the fruit alſo is different, and not appendicled inwardly.

Native of Peru. Annual.

39. Capſules five. Native of the iſland of Bourbon.

40. Root annual. Stem tomentoſe not hairy. Stipules awl-ſhaped, ſpreading. The leaves have a produced point, and vary with and without angles. Peduncle capillary, declined, even, always pendulous. Flower white, before it expands nodding, but afterwards ſtraight from the joint of the peduncle. Capſules obtuſe, compreſſed, rough-haired along the keel[l]: twelve in number, three-ſeeded[k].

Native of Carolina and the Bahama iſlands. Cultivated in 1726, by James Sherard, M. D.[l]

41. Capſules many, without beaks. Native of Perſia.

42. Capſules thirty to thirty-ſix, compreſſed, one-ſeeded globular-umbilicate. Native of Peru, in woods near the river Maragnon. Shrubby[m].

43. This is a ſmall tree, remarkable for its large bell-ſhaped flowers, whitiſh or pale ſulphur-coloured: the column of ſtamens is in five parcels at top: the ſeeds have a bearded umbilicus; the leaves are abſolutely thoſe of *S. reflexa*, except that they are more veined, with cloſer notches. Native of Peru[n].

44. This differs from *S. Abutilon* eſpecially by its very long peduncles, which in that are three times ſhorter than the petioles. Flowers orange-coloured. It is an annual plant, native of the iſland of Mauritius[o].

45. Root annual. Peduncles longer than the petiole, the thickneſs of a thread, permanent, erect after the capſule is fallen. Capſules twenty-ſeven to thirty, awnleſs, one-ſeeded, collected into a globular head[p].

Native of America. Cultivated in 1732, by James Sherard, M. D.[q]

46. Leaves twice as long as they are broad, very tomentoſe, ſerrate, double the length of the petioles. Capſules the ſame ſize as in *S. Abutilon*, twelve-celled, tomentoſe, the cells ending in a lanceolate point the length of the capſule itſelf, not at all cut out at the interior future. Calyx tomentoſe. Peduncles ſhorter than the leaf[r].]

Mr. Miller deſcribes it as the moſt beautiful ſpecies yet known, growing to the height of ſix or ſeven feet, and having a ſmooth woody ſtem, which puts out many lateral branches towards the top. Leaves ſmooth and heart-ſhaped. Flowers axillary, ſolitary, on long peduncles. Corolla large and yellow. Diſcovered by Dr. Houſtoun at La Vera Cruz[s]. [According to Linnæus and Aiton it is a native of Jamaica; the latter ſays, it was cultivated by Mr. Ph. Miller in 1759; but if it be Houſtoun's plant, he muſt have cultivated it before 1733, in which year Houſtoun died. Mr. Miller has a *Sida americana*, which is clearly different from this.]

47. Height about four feet, putting out ſome ſide branches towards the top. Leaves ſoft and woolly, whence it is called in ſome parts of America Marſh-Mallow, and is uſed inſtead of that plant. Flowers axillary, on long peduncles. Annual.

[Leaflets of the calyx folded together or channelled. Fruits black, hairy[t]. Capſules fifteen, two-beaked, three-ſeeded[u].

Native both of the Eaſt and Weſt Indies, Virginia and Siberia. Naturalized in the South of Europe.—Cultivated in 1596 by Gerarde[x].

48. This is an elegant annual plant, thickly covered with a whitiſh-green woolly nap. Stem firm, ſtraight, round, branched, four feet high. Leaves ſharply and equally crenate, on round ſpreading petioles ſhorter than the leaf, having an awl-ſhaped erect ſtipule on each ſide. Peduncles axillary, ſolitary, one-flowered, ſpreading. Corolla yellow, ſpreading very much[y].—Native of Jamaica. Introduced into Europe by Jacquin.

49. Leaves longer than they are wide, as in *S. americana*.

[y] Jacquin.

ricana. Capſule truncate and very hirſute [z]: they are about twenty in number, with three ſeeds in each [a].

Native of the Eaſt Indies. Annual. Introduced about 1768 [b].

Linneus does not ſeem to have diſtinguiſhed the populifolia and hirta from this. Theſe three ſpecies, together with mauritiana (*n.* 44.) ſhould be carefully diſtinguiſhed. *S. mauritiana* and *populifolia* are ſoft; their capſules are twice as large as the calyx, with their horns or beaks ſtanding round like rays: the leaves in the former acuminate-ligulate and toothed; in the latter crenate acuminate. *Aſiatica* and *hirta* have the upper ſurface of the leaf ſcarcely a little rugged; the capſules equal to the calyx, and the ſtipules more permanent. In *hirta* the ſtems, peduncles and petioles are very hairy, and the leaves rounded, acuminate and wrinkled; whereas in *aſiatica* they are cordate and acute or ſcarcely acuminate [c].

50. Capſules from eleven to nineteen, with three ſeeds in each. Annual. Native of the Eaſt Indies, in Bengal.

51. Capſules from fifteen to ſeventeen, with three ſeeds in each. Annual. Native of the Eaſt Indies [d]. The flowers have ſometimes a dark-purple eye [e].

52. Peduncles erect. Capſules terminated by a right angle [f]: from thirteen to fifteen in number, having three ſeeds in each [g]. Native of the Eaſt Indies, Cochinchina, Tanna and New Caledonia. Cultivated in 1739, in the botanic garden at Chelſea [h].

53. Shrubby. Leaves more elongated than in *S. Abutilon*, to which it is allied; and not rounded, as in that. Peduncles commonly one-flowered, but ſometimes having a ſecond flower at the top. Calyxes ciſtoid. Corollas fulvous, three quarters of an inch in diameter. Capſules from ten to twelve (or capſule ten or twelve-celled,) with three ſeeds in each.

Native of Peru, in woods near the river Maragnon. Found by Dombey, who ſent the ſeeds to the Paris garden [i].

54. This very much reſembles the *aſiatica*. Capſules nine, three-ſeeded. Native of the Cape of Good Hope.

55. Capſules fifteen, three-ſeeded. Native of St. Domingo [k].

56. The whole herb is tomentoſe, hoary, and very ſoft. Leaves cordate-ovate, acute, toothed; the primary ones ſomewhat angular at the top, nerved, thickiſh. Stipules awl-ſhaped. Flowers cloſe, in a ſort of panicle, on axillary peduncles at the ends of the branches, yellow. One peduncle one-flowered; a ſecond many-flowered, almoſt leafleſs, bracted, a little longer than the other. Calyxes ſomewhat angular. Capſules ten or twelve, deciduous, ſhortly two-horned [l].

According to Swartz, the peduncles are axillary towards the top of the branchlets, ſhorter than the petioles, ſubſolitary, ſometimes but rarely two or three together, round, tomentoſe, one-flowered. Flowers biggiſh, fulvous. Capſules roundiſh-compreſſed, one-ſeeded.—Native of Jamaica and Hiſpaniola.

57. Capſules five, each terminated by two very long awns. Native of the iſland of Mauritius.

58. Capſules fewer than thirty, truncate, obtuſe, one-ſeeded. Native of the iſland of Bourbon [m].

59. This ſpecies is ſingular for the internal appendixes of the cells. *S. occidentalis* has in like manner a ligule from the bottom of the cell, but it is very different; being ſimple, ſickle-ſhaped, ſurrounding the ſeed vertically; not two-leaved, lanceolate, and ſhorter than the ſeed, as in this. The leaves reſemble thoſe of *S. occidentalis* or *viſcoſa*, but they are hoary with a very ſhort and ſoft nap; not as it were papilloſe, as in *S. occidentalis*; more deeply cordate and not ſtinking, as in *S. viſcoſa*. The joints are generally without prickles [n].

Capſules ten or more, blunt, depreſſed, one-ſeeded. The ſeeds have a linear aril [o].

Native of Peru. Introduced into Europe by Joſeph Pavon, companion to Dombey in travels through Peru and Chili [p].

60. Capſules five, with one ſeed in each. Native of the iſland of Bourbon.

61. Shrubby. Capſules five; ſaid, in the ſpecific character, to be acute; but in the obſervation, to be obtuſe.—Native of Braſil. Cavanilles has two ſpecies, one with a proſtrate ſtem and yellow flowers; the other with an upright ſtem and reddiſh flowers; which Willdenow conſiders as one ſpecies.

62. Capſules five, one-ſeeded. Native of the Eaſt Indies [q].]

63. Stems ſmooth, round, three feet high, ſending out long ſlender branches. Leaves ſmooth, light green, on long foot-ſtalks: the lower ones near three inches long, and almoſt two broad at their baſe. Flowers on very long peduncles, ſmall, and of a whitiſh yellow colour. [Capſules five, two-awned at the top, ſmooth, one-ſeeded. Native of Jamaica, in dry hedges, in the ſouthern parts [r].

64. Capſules five, much leſs than the calyx. Native of Malabar.

65. Capſules five. It varies with hairy or ſmooth ſtems. Native of St. Domingo.

66. Capſules nine, with the awns hairy. Native of the iſland of Bourbon [s].

67. Stem procumbent, filiform, unarmed, very much branched next the ground. Flowers pale yellow, fugacious, three or four lines in diameter. Capſules five, with one ſeed in each. Native of Hiſpaniola [t]. Perennial.

68. Capſules nine. Native of the iſland of St. Domingo. Annual [u].

69. Stem upright, hairy, branched. Capſules nine. Native of the Eaſt Indies [x].

70. Two feet in height, probably annual. Stipules awl-ſhaped, erect. Peduncles ſolitary, one-flowered. Flowers yellow. Capſules five, one-ſeeded. Native of Hiſpaniola.

Among the three-ſpined Sidas, there are perhaps ſome that are mules; the near alliance of the ſpecies or varieties ſeems to indicate this [y].

71. This is very like *S. ſpinoſa*, but the leaves are round. Corollas white with purple ſtigmas, and the tips of the petals purpliſh. The whole plant is bigger [z]. Capſules five [a]. Annual. Cultivated in the Eltham garden before 1732; being raiſed from ſeeds ſent from Bengal, and communicated by P. Collinſon [b].

72. Root annual. Stem ſimple. Calyx hairy. Beaks of the ſeeds, when the corolla falls, prominent in a bundle the length of the calyx [c]. Capſules from ſeven to ten [d].] Flowers ſmall, of a pale obſcure yellow or ſulphur colour. Stem more than three feet high, ſending out ſeveral erect branches from the ſides. Leaves two inches and a half long, and two broad, of a light green colour, ſoft to the touch, on very long hairy foot-ſtalks.

[Cultivated in the Eltham garden before 1732. Native of the Eaſt Indies and the Cape of Good Hope.

73. Capſules five. Native of St. Domingo.

74. Capſules five. Native of Braſil, by Rio Janeiro [e].

75. Stem a foot high and more, ſuffruteſcent, ſimple or branched, erect, round, hirſute. Leaves alternate, nerved, hirſute, hiſpid; on long petioles. Stipules briſtle-ſhaped, at the baſe of the petioles. Flowers terminating, heaped on axillary branchlets, ſubglomerate, on very ſhort pedicels, yellow with a purple eye. Capſules five, oblong, compreſſed. Seeds roundiſh, compreſſed, wrinkled black. Native of Jamaica in dry coppices [f].

76. Capſules from ſix to eleven, three-ſeeded. Native of Jamaica. Annual.

77. Flowers ſmall on corymbed peduncles forming a leafy terminating panicle. Capſules five. Native of St. Domingo [g].

78. Stem herbaceous, erect, two feet high, ſub-

divided, round, rugged, ſomewhat hirſute. Branches ſpreading, almoſt ſimple, filiform. Leaves petioled, alternate, ſubcordate, the ſmaller ones ovate, acute, tooth-ſerrate, nerved, ſomewhat hirſute. Peduncles axillary, ſubdivided, very long, capillary, ſpreading very much; the laſt one-flowered. Segments of the calyx bent back. Corolla dark purple, with the petals ſpreading. Capſules five, compreſſed, roundiſh, acuminate [h].

Native of the calcareous rocks of Jamaica, of Peru and Braſil.

β. Cavanilles diſtinguiſhes the atro-ſanguinea of Jacquin, under the name of *capillaris*. The petals are reflexed. The corollas dark purple. The capſules one-ſeeded, ſcarcely acuminate. It was found by Dombey very abundantly about Lima [i].

79. Panicles terminating, branched, almoſt erect. Petals pale yellow. Capſules five or more frequently ſix roundiſh, gibbous on one ſide, angular on the other, with an awl-ſhaped beak, hoary with very ſmall ſtellate hairs, cloſely converging at top, one-ſeeded. Native of the ſouthern parts of Jamaica in coppices [k].

80. Capſules ſix. Native of Senegal [l].

81. Capſules numerous, one-ſeeded ſqueezed into a ball. Native of St. Domingo.

82. Leaves the length of the petiole or an inch. Raceme ſimple, on a long peduncle. Peduncles one-flowered, with a linear-lanceolate bracte at the baſe. Capſules nine villoſe three-ſeeded. Native of Braſil [m].

83. Fruit inflated. Capſules ten, five-ſeeded. Native of Mexico [n].

84. This is a ſhrub, tomentoſe all over and ſtrong-ſmelling. Leaves ſhortly acuminate. Peduncles one-flowered, equal to the calyx; not ſubbiflorous and ſhorter than the calyx, as in *S. ciſtiflora*. The calyxes are five-cornered, as in that: this circumſtance, together with the leaves being thicker, more tomentoſe and fetid, diſtinguiſh the *craſſifolia* from *mauritiana*, *aſiatica*, *populifolia* and *hirta*. The nerves of the leaves are more manifeſtly pedate than in the others [o]. Capſules nine or ten, three-ſeeded. Native of Hiſpaniola.

85. Capſules ſeveral. Shrubby.

86. Capſules eight three-ſeeded.

87. This is a tree growing to twenty feet in height. Capſules ten to twelve, truncate, acuminate, villoſe. Native of the Caracas.

88. Capſules five. Native of Java.

89. Root annual. Capſules ſeveral, acuminate, connate at the baſe in this and the two following. The flowers in this are of the ſame ſize as in *Malva rotundifolia*.—Native of Mexico and Lima in moiſt places. Linnæus had made this a variety of the next following.

90. Root annual. Flower of the ſame ſize as in *Lavatera Olbia*. Native of Mexico [p].

91. This alſo is annual, and has been confounded with the preceding, but the upper leaves are for the moſt part quite entire. The flowers are of the ſame ſize: but it differs from that in having the upper leaves not three-lobed haſtate, but ovate-lanceolate without any angle; the lower ones three-cornered or ſometimes but more ſeldom five-cornered and elongated, not rounded-cordate. The petals are more emarginate than in the preceding: in *S. haſtata* they are quite entire. Native of Mexico [q].

Mr. Curtis, who conſiders it as the *criſtata*, obſerves, that it grows to the height of three feet or more, producing during the months of july and auguſt a number of bloſſoms in ſucceſſion, which are large and ſhowy; and that the ſtigmas are curious objects, reſembling the heads of Fungi in miniature.

It flowered firſt in november 1725, in Sherard's garden at Eltham, but earlier in the following years: the ſeeds were ſent from Mexico, with thoſe of other rare plants by Stevenſon [r].

Theſe three ſpecies have been ſeparated from the other Sidas by Cavanilles and others, for a reaſon given above; but it does not appear to be a good one.

[h] Swartz. [i] L'Heritier. [k] Swartz. [l] Cavanilles. [m] Willdenow. [n] Cavanilles. [o] L'Heritier. [p] Willdenow. [q] Idem. [r] Dillenius.

92. Lower leaves cordate undivided; upper three-lobed or ſometimes but more ſeldom five-lobed. Peduncles capillary ſhorter than the leaves, of the ſame length or longer. Corolla white. Native of the Cape of Good Hope [s].

93. Native alſo of the Cape, where it was found by Thunberg.

94. Capſules twenty-five, one-ſeeded, winged. Corolla white [t].

L'Heritier, though he inſerts it among the Sidas, regards it as ſo ſingular, as to be almoſt of a ſeparate genus, on account of the feneſtrated arils incarcerating the ſeeds, and the membranaceous placenta ſpringing from the receptacle.—Native of Peru, where it was found by Dombey, in the province of Chancaye, and the ſeeds were communicated to the Paris garden. It is an annual proſtrate plant.

95. Root annual. Leaves exactly like thoſe of *Ricinus*. Capſules eight, gibbous on one ſide, angular on the other, ſpiny or ſubulate-two-horned, collected about a pyramidal ſtriated receptacle, ſhorter than the calyx, one-celled, two-valved, one-ſeeded, opening at top, brown: awns ſet with rigid reverſed hairs, the length of the calyx. Seeds with a one-grooved bump on the outſide, angular within, acute, brown. Native of Peru; found by Dombey, and introduced by him into the Paris garden [u].

96. Leaves nine or ſeven-lobed. Corolla purple or violet [x]. It has the appearance of *Jatropha* or *Urena*. L'Heritier doubts whether this and *ricinoides* be diſtinct ſpecies: he had diſtinguiſhed them, by this having naked capſules, but he afterwards ſaw a ſpecimen with two-horned capſules, and ſtrigoſe awns exactly as in *ricinoides*, which however has the leaves lobed rather than palmate, with the ſegments undivided not runcinate; the flowers alſo are twice as big as in *jatrophoides*, and the herb is more hirſute: neither ſpecies has ſtipules.

Found in the province of Chancaye in Peru by Dombey, who ſent the ſeeds to the Paris garden [y].

97, 98. See *Napæa*.

99. Leaves tomentoſe, white above, ruſeſcent beneath: leaflets cut into three to the very baſe; ſegments lanceolate, obtuſe, quite entire, imbricate: petiole winged with the decurrent ſtipules. Flowers large, blue, ſeſſile on the petiole; whence the trivial name.—Native of Peru. Perennial [z].

Willdenow has ſubdivided the numerous ſpecies of this genus into ſeven ſections, chiefly from the leaves. L'Heritier propoſes rather to adopt the capſules for this purpoſe, as follows.

Sect. 1. Polycoccous ſpecies, with one-ſeeded complete deciduous arils.—Some with five arils only, as *ſpinoſa*, *truncata*, *alba*, *anguſtifolia*, *ſupina*, *urens*. Others with from ſix to ten arils, as *rhombifolia*, *retuſa*, *alnifolia*, *carpinifolia*, *ciliaris*, *cordifolia*, *althæifolia*, *ſuberoſa*, *ricinoides*, *jatrophoides*, *unilocularis*, *pteroſperma*.—Among theſe the greater part is two-horned, as *ſpinoſa*, &c. ſome however are naked, as *urens*; other muricate, as *ciliaris*.

Sect. 2. Polycoccous ſpecies, with one-ſeeded incomplete arils.—*S. unilocularis* has five arils: *criſtata* and *pteroſperma* have many. In the firſt the arils are ſimple, in the ſecond one horned, in the laſt winged-two-eared.

Sect. 3. Multicapſular ſpecies, with one ſeed in a cell: as *paniculata* and *fragrans*, both five-celled: *viſcoſa*, *criſtata*, *nutans*, *occidentalis*, which have more than five cells.

Sect. 4. Multicapſular with ſeveral ſeeds in a cell: as *periplociſolia*, *bernandioides*, *nudiflora*, *triquetra*, which have five cells; *umbellata*, *craſſifolia*, *Abutilon*, *ciſtiflora*, *mauritiana*, *populifolia*, *aſiatica*, *hirta*, *arborea*, *reflexa*, *indica*, *criſpa*, which have many cells.

Among the multicapſular ſpecies are ſome with inflated capſules, as *occidentalis*, *criſpa*, *indica*; others with capſules appendicled within, as *nutans* and *occidentalis*.]

[s] Willdenow. [t] Idem. [u] L'Heritier. [x] Willdenow. [y] L'Heritier. [z] Willdenow.

Digitized by Google

Mr. Miller has nineteen ſpecies of Sida, all from the Weſt Indies.

1. Sida ulmifolia.

Malvinda ulmifolia ſemine roſtrato bidente. *Act. lond.* 399.

Leaves ovate-lanceolate ſerrate, flowers ſolitary axillary, capſules two-beaked.

Stem upright branching three or four feet high. Leaves two inches long and one inch broad, ſeſſile. Flowers on very ſhort peduncles, ſmall, of a pale copper colour. Capſule five-celled, with one ſeed in each cell. Native of America as far north as Virginia. Cavanilles has a ſpecies under this name (n. 34.) and Retzius (n. 2.)

2. Sida carpinifolia.

Stem branched hairy, leaves lanceolate ſerrate, flowers cluſtered axillary, capſules one-beaked.

This cannot well be the *carpiniſolia* of Linneus: (n. 8.) nor does it ſeem to be the *ſpinoſa*, (n. 6.) though Miller refers to Sloane's ſynonym. Both have two-beaked capſules.

3. Sida anguſtifolia, *n.* 2.

Malvinda pimpinellæ folio anguſtiore ſemine bidente. *Act. angl. vol.* 35.

4. Sida pimpinellifolia.

Malvinda pimpinellæ majoris folio, ſemine bidente. *Act. angl.* 399.

Stems ſlender, ſeldom more than a foot high, with a few ſlender branches. Leaves ſmall, heart-ſhaped, ſerrate, a little hoary on their under ſide, on pretty long foot-ſtalks. Flowers ſmall, of a pale yellowiſh colour, coming out ſingly from the axils. Capſules two-beaked.—Perhaps a variety of the preceding.

5. Sida jamaicenſis.

Malvinda profundius ſerrato folio, ſemine tridente. *Act. lond.* 399.

Stem hairy, covered with a dark-brown bark, three feet high, ſending out many ſide branches. Leaves ovate-lanceolate, on long foot-ſtalks, more than two inches long, and an inch and quarter broad, ending in an obtuſe point, and deeply ſerrate. Flowers axillary in pairs, ſeſſile, larger than thoſe of the former ſort, and of a deeper yellow colour: the capſules are larger, and have three horns.—I dare not affirm this to be the *jamaicenſis* of Linneus, n. 9. though we are not to place implicit confidence in the number of horns or beaks to the capſule, as a ſpecific difference.

6. Sida villoſa.

Malvinda carpini folio villoſo, floribus conglobatis ad foliorum alas. *Houſt. mſs.*

Stem woody, upright, hairy, from three to four feet high, ſending out a few ſlender branches towards the top. Leaves a little woolly, ſeſſile, near two inches long, and one inch broad near the baſe, ſubcordate, veined, ſerrate. Flowers axillary in cluſters, ſeſſile. Calyx hairy, acute. Corolla ſmall, pale yellow. Capſules two-beaked.

7. Sida alniſolia. *n.* 21.

8. Sida cordifolia. *n.* 72.

9. Sida hirſuta.

Stems very ſlender, ſtiff, covered with fine hairs, a foot and half high, ſending out a few ſide branches. Leaves roundiſh-heart-ſhaped, two inches long, and an inch and three quarters broad at the baſe, thin, of a light green colour, crenate, on long ſlender hairy foot-ſtalks. Flowers axillary on long peduncles ſolitary. Capſules ending in ten ſtiff acute points or hairs. Corollas ſmall, white.

10. Sida capitata.

See *Malachra capitata.*

11. Sida hirſutiſſima.

Malvinda hirſutiſſima carpini folio longiore, floribus ſingulis ad foliorum alas, ſemine bidente. *Houſt. mſs.*

Stem woody, erect, three feet high, covered with yellowiſh hairs. Leaves ſpear-ſhaped, hairy, ſeſſile, two inches long, and one inch broad in the middle, ſerrate, pale green beneath. Flowers axillary, ſolitary, on ſhort peduncles. Corolla ſmall, white.

12. Sida abutilifolia.

Malvinda abutili folio minore, caulibus hirſutiſſimis, floribus ad foliorum alas. *Houſt. mſs.*

Stems ſlender infirm, three feet high, covered with long white hairs. Leaves ſoft, woolly, heart-ſhaped, crenate, acuminate, little more than an inch long, and three quarters of an inch broad at the baſe, on long ſlender hairy foot-ſtalks. Flowers on long ſlender axillary peduncles, two generally coming out together. Corolla pale yellow.

13. Sida ciliaris, *n.* 22.

14. Sida glabra. *S. arguta, n.* 63.

15. Sida ſericea.

Malvinda ſupina, foliis ſubrotundis ſericeis, ſeminibus non dentatis. *Houſt. mſs.*

Stems ſeveral, ſpreading flat on the ground, nine or ten inches long, ſending out ſeveral ſhort ſide branches. Leaves ovate, ſerrate, fattony, on ſhort foot-ſtalks. Flowers axillary, ſolitary, ſeſſile, ſmall, yellow. Capſules without any beaks or horns.

16. Sida americana.

Malva americana abutili folio, floribus conglobatis ad foliorum alas. *Houſt. mſs.*

Stem woody with a purpliſh bark, two feet high, ſending out ſeveral branches from the lower part. Leaves pretty thick, ſubcordate, crenate, ending obtuſely, woolly beneath, an inch and half long, three quarters of an inch broad near the baſe, veined, on pretty long foot-ſtalks. Flowers pale-yellow, gathered in cluſters ſitting cloſe at the axils. Calyxes hairy, cut into many acute ſegments at the top. Capſules two-beaked.—This is not the *americana* (n. 46.) of Linneus. Miller's Abutilon, n. 16. is that ſpecies.

17. Sida piloſa.

Malvinda carpini folio, flore luteo, caule & averſa foliorum parte villoſo. *Houſt. mſs.*

Stem woody, four feet high, covered with brown hairs, ſending out a few long ſlender branches, which have leaves on the lower part: theſe are ovate, an inch and half long, and three quarters of an inch broad, ſlightly ſerrate, having many longitudinal veins, downy beneath. The branches in the upper part are deſtitute of leaves more than a foot in length, and from their ſides come out peduncles two inches long, ſuſtaining ſeveral ſmall yellow flowers in cluſters, with hairy calyxes cut into ſeveral acute ſegments.—This is not the *piloſa* of L'Heritier, (n. 51:) nor of Cavanilles. (n. 65.)

18. Sida fruticoſa.

Malvinda fruteſcens ulmifolia, ſeminibus ſingulis tribus aculeis lappaceis armatis. *Houſt. mſs.*

Stem ſtrong, ſhrubby, ſix or ſeven feet high, covered with a rough brown bark, and ſending out ſeveral woody hairy branches from the ſide. Leaves ſpear-ſhaped, on long foot-ſtalks, ſix inches in length, and two broad in the middle, ending in acute points, and unequally ſerrate, dark green above, pale beneath. Flowers collected in heads, on long naked peduncles terminating the branches: each head containing ſeven or eight flowers, the petals extending much beyond the calyx: the flowers are of a pale ſulphur-colour when they firſt open, but afterwards fade almoſt to white. Calyxes ſmooth, but terminated by five hairy points which ſtand erect. Capſule ſhort, roundiſh, ſeſſile in the calyx, five-celled, one-ſeeded. Seeds angular, having three ſharp burry teeth, by which they adhere to any thing.—Diſcovered by Dr. William Houſtoun at La Vera Cruz in New Spain.

19. Sida alba.

Malvinda foliis ſubrotundis acuminatis, floribus albis conglomeratis ad foliorum alas. *Houſt. mſs.*

Stem ſhrubby, ſeven or eight feet high, ſending out ſeveral very ſlender branches, extending to two feet or more in length, and bending down at their ends. The joints are two inches aſunder, and at each is one large heart-ſhaped leaf, upon a pretty long foot-ſtalk; the leaves are above four inches in length, and they are two inches and a half in breadth near the baſe; they are ſerrate on their edges, and run out to a long ſharp point; many ſtrong veins riſe from the midrib and diverge towards the borders; they are of a light green above, and pale beneath. Flowers axillary in cluſters; thoſe on the lower part of the branches in cloſe obtuſe ſpikes about an inch in length; but

Digitized by Google

but on the upper part in globular heads, placed nearer together and having no leaves under them; the branches are terminated by one of these heads. The calyxes end in five acute hairy points. Corollas small, when they first open white, but fading to a browniſh colour. Capſule roundiſh, five-celled, ſeſſile in the calyx, two-beaked; having one angular ſeed in each cell. Diſcovered by Dr. Houſtoun in Jamaica.—This is not the *alba* of Cavanilles (n. 4.) nor of Linneus (n. 71.)

There are certainly more ſpecies than are here mentioned, for new ſorts frequently come up in the earth which is brought from the Weſt Indies with other plants. The above are undoubtedly diſtinct ſpecies, having been cultivated ſeveral years, and never changing when raiſed from ſeeds.

Mr. Miller, in the ſeventh edition of his Dictionary, has the ſame Species, with the addition of a twentieth, which is the *Althæa flore luteo* of Sloane, and therefore ſhould be the *Sida althææfolia* of Linneus, (n. 56.) He has alſo ſixteen ſpecies of *Abutilon*, which having omitted in his eighth edition, he probably intended to have transferred them into this genus, and forgot it when he came to the proper place, as he has ſeveral times done in caſes of the ſame ſort.

1. Abutilon *Dod.* S. Abutilon, *n.* 47.
2. A. indicum. *Bauh. hiſt.* S. indica, *n.* 52.
3. A carolinianum reptans, Alceæ foliis, gilvo flore. *Act. lond.* Malva caroliniana, *Lin.*
4. A. americanum, ampliſſimo folio, caule villoſo. *Plum.* S. nudiflora, *n.* 26.
5. A. amer. fructu ſubrotundo pendulo, e capſulis veſicariis criſpis conflato. *Rand.* S. criſpa, *n.* 40.
6. A. althæoides, flore carneo; fructu globoſo. *Dill. elth.* 1. *t.* 1. *f.* 1.

This grows to be a ſhrub of eight or nine feet high. Leaves thick, ſoft, like thoſe of Marſh-Mallow, but deeper cut, crenate, on long petioles. Calyx double; inner one-leafed divided to the middle into five ſegments; outer three-leaved, as in *Malva*. Flowers axillary, peduncled, one, two or more together. Capſules globular.—Native of the iſland of Providence, one of the Bahamas, whence the ſeeds were brought by Mr. Mark Cateſby. The plants flowered the third year from ſeed, in july 1728, in the Eltham garden*.]

7. A periplocæ acutioris folio, fructu ſtellato. *Dill. elth.* 4. S. periplocifolia, *n.* 23.
8. A. americanum, folio haſtato, flore amplo purpureo-cæruleo, longo petiolo inſidente. *Houſt.* Annual.
9. A. amer. flore albido, fructu e capſulis veſicariis planis conflato, pediculo geniculato. *Mart. cent.* 33. Annual; and probably only a variety of *S. criſpa*, *n.* 40. though Miller affirms that he has conſtantly found them to be different.
10. A. amer. ribeſii foliis, flore carneo, fructu pentagono aſpero. *Houſt.*—Annual.
11. A. amer. fruteſcens, folio amplo cordato ſubtus lanuginoſo, floribus amplis luteis. *Houſt.*—A ſhrubby plant, nine or ten feet high, with large heart-ſhaped woolly leaves, and pretty large yellow flowers, which make a good appearance, but are of ſhort duration; there is however a ſucceſſion of them for more than two months.
12. A. fruticoſum aquaticum, folio cordato ſcabro, flore pallide luteo. *Houſt.*—Shrubby, nine or ten feet high. Flowers ſmall.
13. A. amer. frut. foliis cordatis, floribus parvis purpuraſcentibus. *Houſt.*—Shrubby, nine or ten feet high. Flowers ſmall, purple. In the preceding they are pale yellow.—Theſe are natives of Jamaica, La Vera Cruz and the Havannah.
14. A. Lavateræ flore, fructu criſtato. *Hort. elth.* S. dilleniana, *n.* 91.
15. A. arboreum, folio Althææ, fructu villoſo, flore maximo ex rubro flaveſcente. *Houſt.*

This grows to the height of ten or twelve feet, with many lateral branches towards the top, and makes a handſome plant: the ſtems are woody and of a brown colour. Leaves ſmooth, ſhining, heart-ſhaped, on long foot-ſtalks. Flowers very large, at their firſt appearance pale red, but as they expand, changing to yellow; they are of ſhort duration, but there is a ſucceſſion of them for two months, with proper treatment. Seeds covered with a ſhort down ſomewhat like cotton. Mr. Miller had ſeeds of this from the north ſide of Jamaica, from the Spaniſh Weſt Indies, and from the coaſt of Malabar.

16. A. fruteſcens lanuginoſum foliis ſubrotundis, flore amplo luteo patulo. *Houſt. mſs.*—S. americana, *n.* 46.

* Dillenius.

PROPAGATION AND CULTURE.

Theſe plants are many of them annual in England, but ſome are of longer duration in their native countries, and might be ſo here, if they were placed in a warm ſtove in winter; but as moſt of them perfect their ſeeds the ſame year, if the plants are brought forward in the ſpring, few perſons have room in their ſtoves to receive theſe plants, as there are ſo many perennial exotic plants at preſent in the Engliſh gardens, which require a warm ſtove to preſerve them.

They are propagated by ſeeds, which ſhould be ſown upon a moderate hot-bed the beginning of april, and when the plants are come up fit to remove, they ſhould be tranſplanted to another hot-bed, planting them four inches diſtance every way; they muſt be ſhaded from the ſun till they have taken new root, and then they muſt have a large ſhare of free air admitted to them when the weather is mild, to prevent their drawing up weak; they will alſo require water pretty frequently. If the plants thrive well, they will have ſtrength enough to be fit to tranſplant in the open air; for which purpoſe they ſhould be gradually hardened, and the beginning of june they may be taken up with balls of earth to their roots, and planted in a warm ſheltered part of the garden, at about three feet diſtance, obſerving to ſhade and water them until they have taken new root; after which they will require no other care but to keep them clean from weeds. In july the plants will begin to flower, and there will be a continued ſucceſſion of flowers until the froſt comes on. If the ſeaſon proves warm, they will ripen their ſeeds very well in autumn; but leſt theſe ſhould miſcarry by the unfavourableneſs of the ſeaſon, it may be proper to put one plant of each ſort in pots filled with light kitchen-garden earth, placing them in the ſhade till they have taken new root, and then they may be removed to a warm ſituation, where they will thrive very well in a good ſeaſon; but if the ſummer proves cold, they ſhould be placed in a dry airy glaſs-caſe, where they may be kept warm, which will ripen their ſeeds.

Some of the ſpecies will not flower the firſt year: in this caſe the plants muſt be placed in a warm ſtove in autumn, and during the winter they muſt be treated as other tender plants from the Eaſt and Weſt Indies. The following ſummer they will flower and produce ripe ſeeds, but being not of long duration in general, there ſhould be a ſucceſſion of young plants raiſed from ſeed.

47. Is an annual plant hardy enough to come up in the common ground, and to perfect its ſeeds without any trouble. It will not bear tranſplanting, unleſs when very young; the ſeeds therefore are beſt ſown where the plants are deſigned to remain; and if they be permitted to fall, they will come up the following ſpring without any care.

On the contrary ſome of the ſpecies from the Weſt Indies will not flower, or indeed live through the winter in England, unleſs they are preſerved in a ſtove. In ſummer they muſt have as much air as poſſible, and be frequently watered.

[SIDA. See *Malachra* and *Napæa*.]

SIDERITIS (*of Pliny.* Σιδηρίτις *of Dioſcorides. From* σίδηρος, *iron. So named on account of its fancied property in healing fleſh wounds.*)

Lin. gen. n. 712. *Reich. n.* 770. *Schreb. n.* 966. *Tournef. t.* 90. *Juſſ.* 113.

Claſſ. 14. 1. Didynamia Gymnoſpermia.

Nat. order of *Verticillatæ*. *Labiatæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, tubular, oblong, about half five-cleft: *ſegments* acute, almoſt equal.

Digitized by Google

Cor. one-petalled, almoſt equal: *tube* cylindrical, oblong: *throat* oblong, roundiſh: *upper lip* erect, bifid, narrow: *lower lip* trifid; *lateral ſegments* ſharper, commonly ſmaller than the upper lip; *middle ſegment* roundiſh crenate.

Stam. *Filaments* four, within the tube of the corolla, ſhorter than the throat, two of which are ſmaller. *Anthers* roundiſh, two twin.

Pist. *Germ* four-cleft. *Style* filiform, uſually longer than the ſtamens. *Stigmas* two: upper cylindrical, concave, truncate; lower membranaceous, ſhorter, ſheathing the upper.

Per. none. *Calyx* cheriſhing the ſeeds in its boſom.

Seeds four.

ESSENTIAL CHARACTER.

Cal. five-cleft. *Cor.* ringent: upper lip bifid; lower three-parted. *Stam.* within the tube of the corolla. *Stigma* the ſhorter involving the other.

SPECIES.

* *Without bractes.*

1. Sideritis canarienſis. *Canary Iron-wort.*

Leaves cordate obtuſe villoſe, calyxes awnleſs woolly, ſpike long, ſtem erect.]

DESCRIPTIONS, *&c.*

1. Stem five or ſix feet high, ſending out ſeveral woody branches covered with a ſoft down. Leaves on long footſtalks; in young plants often five or ſix inches long, and two and a half broad near their baſe, but in older plants not more than half that ſize; they are very woolly, eſpecially on their under ſide, which is white, but their upper ſurface is of a dark yellowiſh green. The flowers, which grow in thick whorled ſpikes at the end of the branches, are of a dirty white, and appear early in june. The plants frequently produce flowers again in autumn.

[It is a ſhrub with cordate acuminate crenate leaves, green on both ſides. Spikes peduncled, long, nodding: whorls remote; flowers numerous; calyxes rough-haired, mucronate[a].—Native of the Canaries and of Madeira. Cultivated in 1697, by the Dutcheſs of Beaufort.

2. Native of Madeira, where it was found by Mr. Francis Maſſon, and introduced in 1777. It flowers from april to july[b].

3. This is a ſhrub with divaricating branches, very thickly tomentoſe and ſnow-white. Leaves cordate, crenate, tomentoſe on both ſides, obtuſe, very thickly tomentoſe and ſnow-white beneath, green above. Spike from the diviſion of the branches, peduncled, pendulous, tomentoſe, ſnow-white together with the calyxes which are blunt. Flowers about eight in each whorl.—Native of the iſland of Crete or Candia[c].

4. This is an annual plant, with a ſtem decumbent at bottom and then upright, a foot in length. Calyxes ſeſſile, hairy, with awny ſpiny ſegments[d]. Corollas yellow with a ferruginous margin, leſs than the calyx. Whorls ſix-flowered[e]. In rocky ſituations it is upright, in meadows decumbent[f].

Native of Italy, Auſtria and Sileſia. Cultivated in 1758 by Mr. Miller. It flowers in july and auguſt[g].

5. Annual. Calyxes extremely villoſe and ſomewhat pungent, with the uppermoſt ſegment longer than the reſt. Corolla a little longer than the calyx, white with black lips; the upper lip emarginate[h].—The native place of growth not known. Introduced in 1787, by Mr. Zier. It flowers in july[i].]

6. The roots ſeldom continue longer than two years in England. Lower leaves oblong, entire and hairy. Stems ſmooth, hoary, near four feet high, dividing into ſeveral long ſlender branches. Leaves hoary and acute-pointed. Flowers ſmall, whitiſh, in ſmall, compact, remote whorls, having two very ſhort leaves immediately under them, which end in a ſharp ſpine.

[Stems depreſſed, ſtiffiſh. Whorls ſix-flowered. The fifth or upper lobe of the calyx ovate, twice as wide as the others. Corollas like thoſe of Horehound, with the upper lip only emarginate.—Native of the South of Europe[k], and Barbary.

Stems proſtrate or procumbent at the baſe, ſimple or branched at bottom; the branches undivided. Leaves ſpatulate-elliptic, blunt, approximating, ſpreading; nerved, villoſe, produced into the petiole, toothed above. Whorls from bottom to top, ſeſſile. Calyx rigid, villoſe, ſtriated. Corolla a little longer: upper lip linear, ſtanding upright; lower ſpreading, flat, ſlightly three-lobed, the middle lobe rounded. Seeds ſmall, brown, ſhining, blunt, ſlightly three-cornered[l].

Cultivated in 1759 by Mr. Miller. It flowers from june to auguſt[m]; and is generally agreed to be biennial.]

7. This has a ſhort woody ſtem, with a few branches about a foot long. Leaves thick, wedge-ſhaped, very downy and white. Flowers in whorls towards the end of the branches, yellow with ſmooth downy calyxes.

[This little ſhrub has the appearance of a Sage, but is longer. Leaves of Sage, tomentoſe woolly white; the lower petioled, the upper ſeſſile. Flowers yellowiſh-white[n]. The whole plant is covered with a very cloſe white cotton. The root-leaves appear to be quite entire, but on a narrow inſpection they have very minute notches round the edge. Bractes cordate ovate acute, covered with a white nap, a little ſhorter than the calyxes[o].

Native of the Levant. Cultivated in 1739, by Mr. Miller. It flowers from june to ſeptember[p].

8. Stem ſuffruticoſe. Branches a foot long, ſomewhat divided, white-tomentoſe. Root-leaves petioled, ſtem-leaves ſeſſile, all crenate, having a thin nap on them, wrinkle-veined. Bractes cordate, roundiſh-ovate, acuminate, nerved, netted, ſhorter than the calyxes, during the flowering covered with a thin nap, but afterwards almoſt ſmooth, villoſe only at the edge. Corollas yellow, with the tube leſs than the calyx. Quite different from the preceding, by its ſubtomentoſe netted-nerved bractes, and other marks. Native of the Cherſoneſus Taurica.

9. This approaches to the preceding, but differs in having the leaves acute, leſs tomentoſe, quite entire; the ſtem only villoſe, with the whorls very remote; the bractes almoſt ſmooth, mucronate; the tube of the corolla longer than the calyx, with the middle ſegment of the lower lip blunt, not emarginate.

Native place not known, but perhaps from the Levant. Shrubby[q].]

10. Root (perennial, but) ſeldom continuing longer than two years in England. Lower leaves oblong, entire, hairy. Stems near four feet high, dividing into ſeveral long ſlender branches. Stem-leaves hoary, acute-pointed. Flowers ſmall, whitiſh, in ſmall compact remote whorls, having two very ſhort leaves immediately under them, which end with a ſharp ſpine. Calyxes prickly.

[Stem upright, herbaceous. Lower ſtem-leaves petioled, upper ſeſſile, oppoſite, embracing; floral leaves cordate, quite entire, acuminate. Corollas white with ſome rufous veins[r].

Native of the Levant. Cultivated in 1731 by Mr. Miller. It flowers from auguſt to november[s].

11. Stem herbaceous, four-cornered, erect, a foot and more in height, with branches and branchlets like the ſtem and bent in. Leaves acute, pale beneath, dotted above, ſcarcely an inch long: petiole a little ſhorter than the leaf. Spikes of flowers terminating, lanceolate, erect, a finger's length. Bractes ſuborbiculate, acuminate, nerved, imbricate, ciliate not ſpiny, in which it differs from all the reſt. The whole plant is villoſe. Native of Japan[t].

12. This has the habit of Lavender, but it is hoary with a cottony nap. Trunk ſuffruticoſe, for the moſt part decumbent at the baſe; whence ſpring many ſtems or branches, very finely tomentoſe, white, erect, elongated, a foot long, four-cornered. Leaves marked with lines, tomentoſe, white; the lower ones linear-lanceolate, naked above; upper ones linear, more remote; uppermoſt near the whorls ſometimes toothed. Bractes cordate, toothed, ſomewhat ſpiny. Whorls ſix-flowered. Calyxes five-toothed, hoary. Corollas yellow; upper lip erect, linear, often bifid, lower trifid with the middle ſegment four times as wide as the others[u].

It varies with the lower leaves linear-ſpatulate and the upper linear; alſo with the lower linear and the upper oblong or ſpatulate; laſtly, with the leaves quite entire and ſubcordate[x].

Native of Spain. Cultivated in 1748 by Mr. Miller[y].

13. This is an upright hoary ſhrub, with rod-like, upright, ſlender, four-cornered branches. Lower leaves approximating, petioled, narrowed at the baſe, linear-lanceolate; upper remote, twice or thrice as ſhort as the internodes, linear or linear-ſubulate. Flowers ſmall, in whorls, ſeſſile at the top of the branches. Whorls three to five, diſtinct, from four to ſix-flowered. Bractes preſſed cloſe, palmate-toothed; ſegments narrow, acute, mucronate. Calyx cylindrical, tomentoſe, five-toothed: teeth ſetaceous-ſpiny: Corolla pale yellow, longer than the calyx.—Native of Barbary, on ſandy hills near Maſcar[z].

Willdenow ſuſpects it to be a variety of the preceding.

14. Nearly allied to *S. incana*, but differing in having the ſtem herbaceous, and in not being tomentoſe.—Native of Spain, in the kingdom of Valencia[a].]

15. This has a ſhort woody ſtem, with branches a foot and half long. Leaves narrow, ſmooth, an inch long, having a ſtrong ſcent when bruiſed. Flowers yellow, in large ſpiked whorls at the end of the branches.

[Stems many, hairy, ſtraight, hard, a foot high. Leaves on ſhort petioles, ſomewhat hairy, elliptic, with a few and ſometimes no teeth, and three nerves. Whorls cloſe, collected into ſhort ſpikes; with ovate acute leaves interpoſed, acutely ſerrate, the ſerratures and tip ending in yellow ſpinules. Calyx two-lipped, awned, villoſe; the lower lip two-toothed, ſeparate from the upper. Corolla pale yellow, with a few lines on the upper lip, waved, produced into a long appendix, emarginate: middle ſegment of the lower lip emarginate, crenate[b].

Native of Switzerland, Italy and the Pyrenees. Cultivated in 1731 by Mr. Miller. It flowers from june to november[c].]

16. Root perennial. Stems a foot long. Leaves lanceolate, deeply crenate, an inch long and half an inch broad, with ſhort heart-ſhaped prickly bractes. The flowers grow in whorled ſpikes at the end of the ſtem, are yellow, and have an equal prickly calyx.

[Stems perennial a little above the ground, aſcending, ſimple. It differs from *S. hirſuta* in the ſtems being more upright, the leaves above often ſmooth, the corollas yellow even on the upper lip, the ſpikes ovate, not interrupted, the bractes ovate, tooth-ciliate[d].

Haller remarks, that it is very like the preceding, but that the ſtem is more tomentoſe, and the leaves deeply crenate.

Native of the South of France, and of Spain. Cultivated in 1759, by Mr. Miller. It flowers from auguſt to november[e].

β. S. hirta of Roth, which he deſcribes as having the ſtem decumbent at the baſe, the leaves toothed and rough-haired, the bractes cordate, and the ſpikes elongated, is only a variety of the *ſcordioides*, there being intermediate ſpecimens which connect them[f].

17. Stem perennial at the baſe, very much branched, diffuſed, rigid, hirſute. Leaves narrow at the baſe, rigid, hirſute: with two teeth on each ſide, ſpiny. Spikes terminating, an inch and half long. Bractes cordate, tooth-gaſhed, nerved, ſmooth, with the teeth ſpiny. Calyxes on each ſide three, ſhorter than the bracte, hirſute, with the ſegments ſpiny and equal[g].

Plant a foot high. Stems round, hoary. Leaves tomentoſe, on each ſide two or three ſtout ſpiny teeth. Whorls remote, with ſix flowers in each. Calyxes equal with five ſpines. Corollas yellow. It varies with the leaves leſs rigid, and having more teeth. It differs from *S. Scordioides* in having the ſpikes not ovate but interrupted, and the leaves more rigid[h].

[x] Willdenow. [y] Hort. kew. Mill. dict. ed. 5. n. 7. [z] Deſfontaines. [a] Willdenow. [b] Haller. [c] Hort. kew. [d] Linn. ſpec. [e] Hort. kew. [f] Willdenow. [g] Vahl. [h] Alſo.

Native of Spain. Vahl found it common in Caſtille and Arragon.]

18. Root perennial. Stems herbaceous, hairy, trailing, a foot and half long, ſending out branches at the bottom. The upper part of the ſtem has whorls of purple flowers ſtanding pretty far aſunder.

[Stem rigid. Leaves wrinkled and plaited, with three or four ſharpiſh ſerratures. Bractes cordate. Whorls very remote, ſeſſile, ſix-flowered, with the ſtem more hairy between the whorls. Corollas yellow, with the tube curved in, the upper lip linear, ſemibifid, reflexed, erect, ſnow-white, and the lower very ſmall. Calyxes rough-haired, with five equal ſpines. Stamens within the tube[i].

The ſame ſynonym from Caſpar Bauhin is given here and under *cordioides* β.

Native of the South of Europe. Cultivated in 1731 by Mr. Miller. It flowers in june and july[k].

19. Bractes imbricate in four rows, making a ſquare ſpike. Native of Peru. Perennial[l].

20. Root annual. Plant a ſpan high, upright, woolly all over. Stem quite ſimple. Leaves ſubſeſſile, indiſtinctly crenate. Spike longer than the ſtem itſelf, ſeſſile, compoſed of ſix-flowered, remote, very woolly whorls. Corollas dark violet, length of the calyx. Bractes ovate, indiſtinctly ſerrate, woolly[m].]

PROPAGATION AND CULTURE.

The firſt ſort is generally kept in green-houſes in England, but in moderate winters I have had theſe plants live abroad without cover in a warm dry border: however, if they are ſcreened from hard froſt under a common frame, where they may be expoſed to the open air at all times when the weather is mild, and protected from hard froſts, they will thrive better than with more tender treatment. It is propagated by ſeeds which ſhould be ſown in autumn, for thoſe which are ſown in the ſpring ſeldom ſucceed, or if they do, the plants rarely come up the firſt year.

Moſt of the ſorts are hardy enough to thrive in the open air in England: they are propagated by ſeeds, which, if ſown in autumn, will ſucceed better than thoſe which are ſown in the ſpring. The ſeeds may be ſown in ſhallow drills upon a dry ſpot of ground, and in the ſpring when the plants come up, they muſt be kept clean from weeds; and when the plants are fit to remove, part of each ſort may be drawn out, and planted in a bed at about nine or ten inches diſtance, which will give thoſe which are left in the ſeed-bed room to grow. The plants which are removed ſhould be ſhaded and watered until they have taken new root, after which they will require no other care but to keep them clean from weeds till the following autumn, when they ſhould be tranſplanted to the places where they are to remain. None of the ſorts ſhould be planted in rich ground, for that will cauſe them to grow ſo luxuriant in ſummer, that the froſt or much wet will deſtroy them in winter.

The annual ſorts (n. 4. 5.) ſhould not be removed, but the plants thinned and left in the place where they were ſown, keeping them clean from weeds.

The ſixth and ſeventh ſorts, though properly greenhouſe plants, will often live through the winter in the open air, eſpecially if their ſeeds are ſown upon dry rubbiſh; for when either of theſe happen to grow in the joints of old walls, they will endure the greateſt cold of this country, therefore their ſeeds ſhould be ſown in ſuch places. The ſeventh ſort does not produce good ſeeds in England, therefore this is propagated by ſlipping off the heads, planting them in a ſhady border during the ſpring or ſummer months, which will readily take root; ſome of theſe may then be taken up and put into pots, that they may be ſcreened under a frame in winter.

Sideroxylum americanum, ſ. lignum duritie ferrum æmulans. *Pluk. phyt. t.* 224. *f.* 2.

DESCRIPTION, *&c.*

This is a tall branching tree, with ovate-lanceolate, acute, quite entire, ſhining, petioled, oppoſite leaves, half a foot long. Peduncles axillary, very ſhort, often three-floweted. Flowers ſmall, roſe-coloured on the outſide, white within[a].

Branches ſmooth, below round, above ſlightly four-cornered, compreſſed at the top. There is a little bracte on each ſide the baſe of the pedicels. The corolla is often changed, perhaps by ſome inſect, into an oblong bag, half an inch in length, fleſhy, hollow within, ending in a point at top, and having the appearance of a fruit[b].

Jacquin found it in the mountain woods of Martinico; and Ryan in Montſerrat.

Lin. ſyſt. 232. *Reich.* 1. 538. *Willd.* 1. 1091. *mant.* 48.
Spiny, leaves deciduous elliptic.

DESCRIPTIONS, *&c.*

1. Royen remarked that the flowers have no teeth between the ſtamens. It is a native of Africa.]

2. At the Cape of Good Hope, where this tree is a native, it riſes to the height of an Engliſh Apple tree; but in Europe it is rarely more than eight or ten feet high. The wood is ſo heavy as to ſink in water, and being very cloſe and hard, the name of Iron-wood has been given it, and hence the generic appellation of Sideroxylon. It divides into many branches, which are covered with a ruſſet bark. Leaves about three inches long, and an inch and half broad in the middle, ending in points at both extremities, placed without order on the branches, having footſtalks an inch long: they are ſmooth, of a lucid green, and continue all the year. The flowers come out in cluſters from the ſide of the branches, upon ſhort footſtalks, which branch out into ſeveral ſmaller, each ſuſtaining a ſingle flower, which is ſmall and white[c].

[Cultivated in 1729, by James Sherard, M. D.[d] It flowered that year in the Eltham garden, in the month of july: but had been there about ſeven years, and was obtained firſt from Dr. Uvedale's garden at Enfield, and afterwards from Holland[e].

3. This tree bears a great reſemblance to the preceding: it has thick branches like that, but without any ſtreaks or warted dots. The leaves are perennial; and the peduncles very ſhort, but not round. Burman's figure repreſents this rather than the inerme. There are no teeth between the ſtamens.—Native of the Cape of Good Hope[f]. Introduced in 1783, by Mr. John Græffer[g].

Sideroxylon tenax and fœtidiſſimum, according to Swartz, ought to be referred to the genus Bumelia, on account of the form of the nectary, and the fruit being a one-ſeeded drupe.

The former is a native of Carolina, and is thus deſcribed in Linneus's mantiſſa.—Height twenty feet, with a white bark, and very tough branches. Buds alternate, from each proceed numerous peduncles, an inch long, one-flowered. Leaves within or between the peduncles five or ſix, petioled, oblong, bluntiſh, quite entire, ſubtomentoſe beneath, the length and breadth of a finger, firm, annual. Flowers ſmall.

[c] Mill. fig. [d] Hort. kew. [e] Hort. elth.
[f] Linn. mant. [g] Hort. kew.

Calyx

Calyx ovate, with five ovate blunt leaflets, the outer ones wider and converging. Tube of the corolla length of the calyx: border five-parted; the parts ovate, ſhorter than the calyx: nectary in the throat of the corolla, a little leſs than the corolla, five-parted; leaflets trifid, the middle generally longer. Stamens length of the corolla. Germ five-cornered. Style and ſtigma ſimple. Drupe oval. Nut ovate, ſhining, with two holes at the baſe, ſeparated by an arched ſeptum. Stature of Chryſophyllum or Achras: it varies with very ſhort ſpines here and there on the branchlets. It is the Chryſophyllum carolinenſe of Jacquin's obſervations, and Bumelia tenax of Willdenow's ſpecies.

The latter, Sideroxylon fœtidiſſimum, is a native of St. Domingo; and has the leaves ſubalternate, lanceolate-oblong, obtuſe, ſubemarginate, ſhining: the peduncles axillary, one-flowered, abundant in cluſters. It is Bumelia fœtidiſſima of Willdenow's ſpecies.]

Miller, beſides the *inerme*, has a ſecond ſpecies, which he names *Sideroxylon oppoſitifolium*. He ſays it grows more upright and regular; and that the leaves are ſmaller, more pointed, and placed oppoſite on the branches.

[4. This is a ſmall ſhrub, native of the Cape of Good Hope. Thunberg found it on the Tafelberg[u].

5. Native of New South Wales, where it was found by Sir Joſeph Banks, and introduced in 1772[x].

6. Native of the Cape of Good Hope.

7. A ſmall tree, with an erect trunk, covered by an aſh-coloured bark. Branches erect, very numerous. Leaves alternate, on ſhort petioles, oval a little ſcolloped; when full grown ſmooth, when young covered with much ruſt-coloured down; from three to five inches long, and an inch and half broad. Peduncles axillary, numerous, ſhort, downy, bowing, undivided, one-flowered. Flowers ſmall, dirty white. Calyx inferior, five-leaved: leaflets imbricate, downy, permanent. Tube of the corolla ſhort, downy within: margin five-parted; ſegments ſpreading, half-lanceolate, acute, waved. Nectary of five petals, alternate with the filaments, waved, length of the ſtamens. Berry oval, ſize of an Olive, with one or two ſeeds only in general, though there are the rudiments of five.

Native of the Eaſt Indies, on the tops of mountains chiefly; flowering during the hot ſeaſon[y].

8. Native of Canada. Perhaps a ſpecies of *Bumelia*, Wangenheim having deſcribed the fruit to be a dry drupe containing one ſeed[z]. Cultivated in 1758 by Mr. Miller[a].

9. This is a tree with axillary ſolitary ſpines and alternate leaves. Peduncles axillary, one-flowered, very many, a little longer than the petioles. Calyx five-cleft, obtuſe. Corolla funnel-form, five-cleft, obtuſe; with the ſegments concave, ſcarcely unfolded. Nectary five-leaved, ſerrate, ſhort, each lobe to each ſegment of the corolla. Stamens ten, awl-ſhaped, length of the nectary; anthers ſagittate. Germ globular: ſtyle filiform; ſtigma very ſmall. Berry black, globular, from three to five-celled, commonly abortive.—It reſembles the preceding, yet differs much either in ſpecies, or from culture[b].

Native of South America.

Of *Sideroxylon ſpinoſum* there is no ſpecimen in Linneus's herbarium ſufficiently perfect to aſcertain the ſpecies. From Clifford's herbarium, now in the poſſeſſion of Sir Joſeph Banks, it appears, that the Argan of Morocco, had been taken up by Linneus in the Hortus Cliffortianus under this name. This Argan or Olive tree of Morocco, is the Rhamnus pentaphyllus, firſt publiſhed by Linneus (app. ſyſt. nat. ed. 12.) under the name of Rhamnus ſiculus; as appears from the ſpecimen in Linneus's herbarium, compared with ſpecimens in Sir Joſeph Banks's herbarium, from Morocco[c].

Linneus ſeems to have confounded *Elæodendrum Argan* and *Flacourtia ſepiaria* under this name of *Sideroxylon ſpinoſum*, which are both of very different genera from this. Willdenow received the latter of theſe two plants from Koenig, under the name of *Sid. ſpinoſum*. The ſynonyms of Commelin (hort. 1. 161. t. 83.) Plukenet (phyt. t. 202. f. 2.) Rheede (5. 77. t. 39.) and Burman (ind. 59.) belong to *Flacourtia ſepiaria*[d].

See *Elæodendrum Argan*.

For the other ſpecies of Sideroxylon, ſee *Chryſophyllum*, *Curtiſia* and *Olea*.]

PROPAGATION AND CULTURE.

Theſe plants being natives of warm countries, cannot be preſerved in England, unleſs they are placed in a moderate ſtove. They are propagated by ſeeds, when theſe can be procured from abroad. Theſe muſt be ſown in pots filled with light rich earth, and plunged into a good hot-bed in the ſpring, in order to get the plants forward early in the ſeaſon. When the plants are fit to tranſplant, they ſhould be each put into a ſeparate ſmall pot filled with good earth, and plunged into a freſh hot-bed while they are young. In winter they muſt be plunged into the tan-bed in the ſtove, and treated in the ſame manner as has been directed for tender plants from the ſame countries. As the plants obtain ſtrength, they may be treated more hardily, by placing them in a dry ſtove in the winter, and giving them a greater ſhare of free air in ſummer; and when they have obtained ſtrength, they may be placed abroad in ſummer in a ſheltered ſituation.

I have propagated them by layers, but theſe were two years before they had made good roots; and ſometimes they will take from cuttings, but this is a very uncertain method, nor do the plants ſo raiſed ever grow ſo vigorouſly as thoſe which come from ſeeds.

SIGESBECKIA. (*So named from John George Siegeſbeck, a German, Prefect of the Peterſburgh garden. Author of* Primitiæ Floræ Petropolitanæ. 1736. Rigæ 4°.—De Maianthemo Lilium convallium nuncupato. Petrop. 1736. 4°.—Botanoſophiæ verioris ſciagraphia. Petrop. 1737. 4°.—Vaniloquentiæ botanicæ ſpecimen. Petrop. 1741. 4°.)

Lin. gen. n. 973. *Reich. n.* 1057. *Schreb. n.* 1320, *Gærtn. t.* 168. *Juſſ.* 187.

Claſſ. 19. 2. Syngeneſia Polygamia Superflua.

Nat. order of *Compoſitæ Oppoſitifoliæ.—Corymbiferæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Common exterior* five-leaved: *leaflets* linear, round, ſpreading very much, longer than the flower, permanent: *interior* ſubquinquangular; *leaflets* many, ovate, concave, obtuſe, equal.

COR. *Compound*, half-radiate. *Corollets* hermaphrodite many in the diſk: *female* five or fewer in the ray, only on one ſide of the flower.

Proper of the hermaphrodite funnel-form, exceeding the calyx in length, five-toothed or three-toothed. *Female* ligulate, wide, three-toothed, very ſhort; or funnel-ſhaped, trifid, the interior diviſion deeper.

STAM. in the Hermaphrodites: *Filaments* five or three, very ſhort. *Anther* cylindrical, tubular.

PIST. in the Hermaphrodites: *Germ* oblong, curved in, ſize of the calyx. *Style* filiform, length of the ſtamens. *Stigma* bifid.—In the *Females: Germ* oblong, curved in, ſize of the calyx. *Style* filiform, length of the hermaphrodite. *Stigma* bifid.

PER. none. *Calyx* unchanged.

SEEDS in the Hermaphrodites ſolitary, oblong, obtuſely four-cornered, thicker above, obtuſe, naked. *Pappus* none.—In the Females very like the others.

REC. chaffy: *chaffs* very like the ſcales of the calyx, concave, wrapping up the ſeeds on one ſide and deciduous.

ESSENTIAL CHARACTER.

Cal. exterior five-leaved, proper, ſpreading. *Ray* halved. *Pappus* none. *Recept.* chaffy.

DESCRIPTIONS, *&c.*

1. Plant annual, near four feet high, ſending out many branches. Flowers terminating, ſmall, yellow.

[Stem upright. Leaves ovate, acuminate at both ends, finiſhing in the petioles, oppoſite, three-nerved, veined, ſerrate. Branches from each upper axil, ſhorter than the ſtem. Peduncles terminating and lateral from the upper branches ſolitary, brachiate, ſuſtaining a fulvous flower, in form of a ſpider, with a ſpreading involucre, fenced by five hiſpid rays, or hairs having a clammy head on the top of each. When the ripe ſeeds are gathered, they move in the hand as if they were alive. It is remarkable for having the ray of the flower on one ſide, as in Milleria[e]. Receptacle narrow, flat. Seeds inverſely pyramidal, rugged with tubercles, glutinous, brown, bald, ſmooth, of a livid lead-colour, or brown[f].

Native of India, China, Media, Otaheite and New Zealand. Cultivated in 1730, by Mr. Miller. It flowers in july and auguſt[g].

2. Stem ſtiff and ſtraight. Leaves oppoſite, lanceolate-ovate, triple-nerved, ſerrate, running down on both ſides along the ſtem, which thence has four membranaceous angles, ſubtomentoſe beneath. Peduncles terminating, brachiate. Calyx oblong. Receptacle naked. Corolla radiate, with a ſingle, ligulate ray, bifid at the top. The ſeeds have a pappus on each ſide of two chaffs[h].

Cultivated in 1731 by Mr. Miller; who has omitted it in the later editions of his Dictionary. It flowers in october and november, and is perennial[i]. See *Phaethuſa.*

3. Plant annual, three feet high. Stem very much branched, round, ſlightly ſtriated, ſomewhat villoſe, jointed, the thickneſs of a reed, duſky purple: branches oppoſite, when flowering dichotomous, diffuſed, ſtriated, marked with rings, villoſe, purpliſh. Leaves oppoſite, embracing, remote, ſpreading, ovate, acute, unequally ſerrate, with appendages ſurrounding the ſtem at the baſe, three-nerved, veined, wrinkled, the upper ſurface ſhining, the lower paler, two inches long and fifteen lines wide. On the flowering branchlets the leaves are alternate, ſeſſile, but not margined at the baſe, ovate-lanceolate, gradually leſs and leſs. Panicle terminating, very looſe, leafy, dichotomous, from the ſtem itſelf. Flowers within the forkings of the branchlets or oppoſite to a leaf, ſolitary, peduncled, the upper ones cloſely heaped in a ſort of corymb, herbaceous with a yellow diſk. Peduncles erect, filiform, villoſe, four lines long. Calyx glandular-hairy; exterior five-leaved, interior ten-leaved, converging, angular. Compound corolla almoſt uniform, reſembling a floſcular flower, globular; having many hermaphrodite florets in the diſk, and five female in the ray. Seeds to both florets, obovate, curved in, ſomewhat rugged, brown.—This ſpecies is diſtinguiſhed at firſt ſight from the *orientalis* by its floſcular-like flowers, and dichotomous, diffuſed branches. Perhaps it is the only plant which is triandrous, in the claſs Syngeneſia.

Native of Peru, whence it was ſent by Dombey[k].

[e] Linn. cliff. [f] Gærtner. [g] Hort. kew. [h] Linn. ſpec. & mant. [i] Hort. kew. [k] L'Heritier.

It is an annual plant, flowering in june and july; and was introduced in 1784 by Chev. Thunberg[l].]

PROPAGATION AND CULTURE.

1. Sow the ſeeds on a hot-bed, and ſet out the plants in a warm border the beginning of june, ſupplying them with water in dry weather.

[2. Is a perennial hardy plant.

3. Soon ripens its ſeeds, and may be propagated by them or by cuttings.

Ocymoides noctiflorum. *Camer. hort.* 109. *t.* 34. *Beſl. eyſt. æſt.* 7. *t.* 12. *f.* 3.

Stem dichotomous, petals bifid obtuſely crowned, calyxes ten-angled, teeth nearly equal to the tube.

[31. Silene ornata. *Dark-coloured Catchfly.*

Ait. kew. 2. 96. *Curt. magaz.* 382. *Willd. ſpec.* 2. 702.

Calyxes of the fruit oblong keeled hairy, petals bifid, leaves lanceolate pubeſcent viſcid flat, ſtem viſcid.

32. Silene undulata. *Waved-leaved Catchfly.*

Ait. kew. 2. 96. *Willd. ſpec.* 2. 702.

Calyxes of the fruit club-cylindrical hairy, petals bifid, leaves lanceolate pubeſcent waved, ſtem aſcending.

33. Silene virginica. *Virginian Catchfly.*

Lin. ſpec. 600. *ſyſt.* 421. *Reich.* 2. 352. *Willd.* 2. 702. *Gron. virg.* 151. *Pluk. phyt. t.* 203. *f.* 1. (Lychnis.)

Calyxes of the flower cylindrical villoſe, panicle dichotomous.

34. Silene antirrhina. *Snap-dragon-leaved Catchfly.*

Lin. ſpec. 600 *Reich.* 2. 352. *Willd.* 2. 702. *hort. upſ.* 114. *Gron. virg.* 50. *Dill. eltb.* 422. *t.* 313. *f.* 403. (Viſcago.)

Leaves lanceolate ſubciliate, peduncles trifid, petals emarginate, calyxes ovate.

35. Silene ſedoides. *Sedum-like Catchfly.*

Lin. ſpec. ed. Willd. 2. 703. *Jacqu. collect. ſuppl.* 112. *t.* 14. *f.* 1.

Lychnis cretica maritima minima portulacæ ſylveſtris folio. *Tournef. cor.* 24.

Glandular-hairy, calyxes club-ſhaped, petals emarginate, leaves oblong-obovate ſomewhat fleſhy.

36. Silene apetala. *Apetalous Catchfly.*

Lin. ſpec. ed. Willd. 2. 703.

Calyxes ovate pubeſcent, flowers apetalous, leaves lanceolate pubeſcent.

37. Silene rubella. *Small red-flowered Catchfly.*

Lin. ſpec. 600. *Reich.* 2. 352. *Willd.* 2. 703. *hort. upſ.* 112. *Dill. eltb.* 423. *t.* 314. *f.* 406. (Viſcago.)

Erect even, calyxes ſubglobular ſmooth veined, corollas unopen.

38. Silene inaperta. *Small unopen-flowered Catchfly.*

Lin. ſpec. 600. *Reich.* 2. 352. *Willd.* 2. 703. *Allion. pedem. n.* 1577. *Dill. eltb.* 424. *t.* 315. *f.* 407. (Viſcago.)

Stem dichotomous panicled, calyxes even, petals very ſhort emarginate, leaves ſmooth lanceolate.

39. Silene clandeſtina. *Clandeſtine Catchfly.*

Lin. ſpec. ed. Willd. 2. 703. *Jacqu. collect. ſuppl.* 111. *t.* 3. *f.* 3.

Calyxes ovate ten-angled pubeſcent, petals bifid erect a little longer than the calyx, leaves oblong-lanceolate ciliate.

40. Silene portenſis. *Oporto Catchfly.*

Lin. ſpec. 600. *Reich.* 2. 353. *Willd.* 2. 704.

Stem dichotomous panicled, calyxes ſtriated, petals bifid, leaves linear.

L. ſilv. minima. *Tabern. ic.* 297.

Hirſute, leaves narrow-lanceolate, flowers racemed diſtinct ſeſſile, teeth of the calyx awl-ſhaped, capſules acuminate erect.

59. Silene reticulata. *Netted Catchfly.*
Desfont. atlant. 350. *t.* 99.

Smooth viſcid, leaves narrow-lanceolate, peduncles two or three-flowered, calyx club-ſhaped netted, petals linear emarginate.

60. Silene bipartita. *Cloven-petalled Catchfly.*
Desfont. atlant. 352. *t.* 100.

Lower leaves ſpatulate, flowers racemed directed one way nodding, petals two-parted.

61. Silene Pſeudo-atocion.
Desfont. atlant. 353.

Loweſt leaves obovate, flowers in bundles terminating, calyxes club-ſhaped, petals linear quite entire.

62. Silene ramoſiſſima. *Branched Catchfly.*
Desfont. atlant. 354.
Lychnis minima hiſpida noctiflora. *Magn. bot. app.* 308.

Pubeſcent viſcid very much branched, leaves narrow-lanceolate, peduncles from one to three-flowered, calyxes ovate, petals bifid, capſules ſubſeſſile within the calyx.

63. Silene Arenaria. *Sandwort Catchfly.*
Desfont. atlant. 354.
Lychnis maritima gadenſis anguſtifolia. *Tournef. inſt.* 338.

Villoſe viſcid, leaves linear-lanceolate bluntiſh, flowers looſely racemed, petals bifid, capſules within the calyx pedicelled.

64. Silene arenarioides. *Sandwort-like Catchfly.*
Desfont. atlant. 355.

Pubeſcent, leaves narrow-linear, peduncles from one to three-flowered, calyxes ten-ſtriated villoſe, petals bifid, capſules round pedicelled.

65. Silene cinerea. *Aſh-coloured Catchfly.*
Desfont. atlant. 355.

Lower leaves ovate, flowers racemed ſubſeſſile ſolitary two or three together, calyx pubeſcent ten-ſtreaked, petals bifid.

66. Silene patula. *Spreading Catchfly.*
Desfont. atlant. 356.

Viſcid, branches panicled-ſpreading, lower leaves on long petioles ovate acuminate, peduncles ſubtriflorous, calyx elongated, petals ſemibifid.

DESCRIPTIONS, *&c.*

1. Root annual, fibrous. Stem branched, ſpreading, flexuoſe, round, leafy; branches ſomewhat ſpiked, erect. Leaves linear-lanceolate acute. Flowers axillary, ſolitary, peduncled, white. Calyx nerved, hirſute, cylindrical, finally ventricoſe. Border of the petals elliptic, emarginate, having ſometimes a fleſh-coloured ſpot. Capſules ovate, rigid, the upper ones commonly erect [a]. They cannot be conſidered as pendulous, though Dillenius makes that a character of this ſpecies. The lower ones indeed diverge from the ſtem, and are finally bent downwards.

Linneus diſtinguiſhes this from the next ſpecies thus. The petals in this are not crenate; in the following they are both crenate and emarginate. Lower leaves obovate-lanceolate, towards the baſe ciliate. Calyxes not hairy, but muricated at the angles with reflex ſcarcely conſpicuous prickles [b].

Native of England and France, in ſandy fields; flowering in june and july. Lobel was the firſt who remarked this plant about Colcheſter and elſewhere. Dale found it in the ſame place, and alſo about Bocking in the ſame county of Eſſex. Johnſon remarked it about Canterbury. Mr. Dent, near the Devil's ditch in Cambridgeſhire. Mr. Relhan in Chippenham gravel-pit, and by the turnpike near Newmarket, in the ſame county. Dr. Smith, at Lakenham and Coſſey near Norwich. Hudſon and Curtis, about Coombe wood in Surry. About Weybridge in the ſame county. Mr. Curtis ſaw it alſo in great abundance in cornfields near Newport in the Iſle of Wight. In Scotland, it has been found between Dundee and St. Andrew's, by Mr. Browne: there and near Perth, by Mr. Mackay.

[a] Smith. [b] Spec.

2. Calyxes of the fruit bent back horizontally, and very hairy. Corolla undivided, crenate, fleſh-coloured. It is an annual plant, native of Portugal [c], and Barbary. Differs from the next in having crenate pale purple petals, horizontal divaricating fruits, and the whole plant rough with ſpreading hairs [d].

3. From a ſmall fibrous annual root ariſe ſeveral flaccid ſpreading ſtems, round, hairy, and a little viſcid; as are alſo the leaves in a ſlight degree. Numerous flowers ſpring in an alternate order from the boſoms of the upper leaves, on pedicels which are erect, or but little divaricated even when the fruit is ripe. The petals are remarkable for the deep red ſpot in their centre, like a drop of blood; whence the trivial name *quinquevulnera*. *S. anglica* has ſometimes pale reddiſh ſpots on the petals, but theſe are emarginate in that ſpecies; which is alſo more viſcid than this, and paler-coloured in all its parts [e]. All the capſules in *quinquevulnera* are for the moſt part erect, though the lower ones are ſometimes bent back. The leaves are elliptic-lanceolate [f].

Native of the South of Europe, Siberia, and Barbary. Mr. Hudſon is our authority for conſidering this pretty plant as of Britiſh growth; he having mentioned it as growing in ſandy fields about Wrotham in Kent. It has been long cultivated in our Engliſh gardens under the name of dwarf Lychnis, and may frequently be found almoſt naturalized on heaps of rubbiſh. It continues in flower from june till the end of auguſt, and produces great plenty of ſeeds [g].] Theſe were formerly ſown in drills on the edges of borders, with ſeveral other low annual plants; but being of ſhort duration, they were ſoon rejected for this purpoſe. [Ray cultivated it in his little garden at Cambridge, and ſays that the plants which roſe from ſeeds ſelf-ſown in autumn were eighteen inches high.

4. Root ſimple, perpendicular, filiform. Stems ſomewhat branched, ſeveral, aſcending, a finger's length, round, pubeſcent. Root-leaves roundiſh-ſpatulate, pubeſcent. Stem-leaves oblong, acute, pubeſcent. Flowers erect, axillary, alternate, on very ſhort peduncles. Calyx pubeſcent, club-ſhaped, ten-ſtreaked; the teeth ciliate-hairy about the edge. Petals bigger than the calyx, deeply two-parted; the ſegments obovate. Crown two-parted. Capſule elliptic, pedicelled. Flower bigger than in the preceding.—Native of the iſland of Candia [h].

5. Root white, annual, round, not very fibrous. Stem round, divided from the bottom alternately or forked into procumbent branches, not commonly ſimple. The whole plant is ſilky and ſomewhat hoary. Leaves conjugate, embracing. Flower peduncled, terminating each branch. Peduncle length of the calyx and of the leaves. Calyx club-ſhaped, with ten ſtreaks and angles, whitiſh-tranſparent; the larger angles produced into ſegments, below which it is inflated. Claws of the petals linear, ſhining, higher than the calyx; border cordate, pale roſe-coloured, cloven beyond the middle, blunt at the end: ſcales of the crown erect, acute.

Native of Piedmont, on the ſandy coaſt between Oneglia and Porto Maurizio [i].]

6. This is an annual plant with a low branching ſtem, which ſeldom riſes more than eight or nine inches high, and is ſmooth. Leaves very narrow, and ſmooth, placed by pairs. The ſtems are terminated by ſpikes of dark purple flowers ſtanding alternate, and opening in the evening, but cloſely ſhut during the day.

[Lower leaves obovate, concave, rigid. Flowers ſeſſile, from oppoſite bractes alternate, alternately flowering. Petals white, bifid, biggiſh, greeniſh beneath, and not red after flowering. It reſembles *Cucubalus reflexus*, but has a more branched and higher ſtem, with the petals ſpreading beyond the calyx [k].

Native of France and Spain. Cultivated in 1683, by Mr. James Sutherland. It flowers in july [l]. According to Mr. Miller it grows naturally in Sicily and

[c] Linn. ſpec. [d] Desfontaines. [e] Engl. bot.

[i] Allioni. [k] Linn. ſpec. [l] Hort. kew.

Digitized by Google

at the Cape of Good Hope. Linneus adds Penſylvania to the European ſtations.

7. This is more viſcid and hairy than the *anglica*. (*n*. 1.) It is more branched and grows higher, from a foot to two and three feet. The lower leaves are wider, the upper narrower and longer. Flowers axillary, on ſhort peduncles, void of ſcent, opening in the day time, green in the middle, very pale purple above, ſtreaked with deeper purple veins beneath. Calyxes ſtriated, rough with many longiſh hairs [m]. It is an annual plant, native of France and Switzerland: flowering here in may. Cultivated by Sherard at Eltham in 1732; by ſeeds ſent from Holland.

8. This is an annual, upright plant. Lower leaves roundiſh, upper narrower and longer, with the midrib ſcarcely viſible. Calyx marked with ten green ſtreaks, hirſute with long hairs, and ſlightly viſcid, as are alſo the ſtems and leaves. Flower like that of *S. anglica*, but ſmaller, pale purple, with the crown ſcarcely viſible. Capſules erect, not in ſo long a row as in *S. anglica*, and the whole plant leſs hirſute and viſcid; the petals alſo are emarginate [n].

Native of the South of Europe. Cultivated by Sherard in 1732.

9. Leaves narrow; lower three inches long, and ſcarcely an inch wide; on the ſtem gradually ſhorter and narrower; hairs on the upper ſurface fewer and longer, on the under more frequent and ſhorter. Stem eighteen inches high, round, weak, hairy, red towards the bottom: joints frequent, with a pair of ſeſſile leaves at each, from a wide baſe contracting to a point. Flowers ſolitary and alternate from the upper axils, on ſhort peduncles, the lower ones being ſcarcely half an inch long, very ſmall, fugacious, and ſeldom expanding, uſually white, but ſometimes purple on the ſame plant. Calyxes rough with long hairs. Petals narrow, ſcarcely bifid, the edges bent inwards [o].

It is an annual plant, native of the South of Europe. Ray had the ſeeds from Sir Hans Sloane, and cultivated it before 1688.

Linneus remarks that it is allied to *Cucubalus reflexus*; to which (as he ſays) Ray united it; but that, on being ſown, they appeared to be different. I cannot find that Ray any where confounds theſe two plants.

10. Root perennial. Bottom leaves ſpread in a ring, oblong, narrow, ſmooth, without veins. Stems two feet high, and ſometimes more, round, ſmooth, green in the lower part, purpliſh in the upper, with a glaucous bloom, not at all viſcid. From the middle upwards at each joint ſpring round peduncles in pairs, tinged with purple, ſubdivided into more ſlender ones, each of which bears a flower or two. Calyxes oblong, round, ſmooth, glaucous, divided into five ſhort ſegments at the top. Corollas herbaceous or greeniſh yellow, of five narrow petals, divided to the middle, without any viſible crown, opening only at night. Capſule rigid, membranaceous, ventricoſe, opening in ſix parts. The flowers at firſt form an oblong pendulous ſpike; afterwards become looſe in a thin nodding panicle; and when the ſeeds ripen, the whole panicle is upright. It is known by the leaves and ſtems being ſmooth and not viſcid; the petals narrow and herbaceous [p].

Native of Germany. Cultivated in the Eltham garden in 1732. The ſeeds came from Boerhaave, who ſent Sherard rare plants and ſeeds every year. It alſo came from Paris [q].

11. Root ſomewhat woody, perennial. Stems ſeveral, ſimple, (according to Mr. Woodward, frequently branched from the root,) a foot or more in height, erect, leafy, round, pubeſcent, jointed at the baſe, viſcid in the upper part, terminating in a forked panicle, the ſummit and branches of which all droop towards one ſide. Leaves lanceolate acute, quite entire, pubeſcent on both ſides, of a paleiſh green; the radical ones inclining to obovate, and forming thick tufts. Flowers drooping, white, of a delicate texture. Calyx ten-ribbed, half an inch long, ſlightly pubeſcent, ſometimes purpliſh, as are very generally the long foot-ſtalks of the leaves at their inſertion, and the baſe of the ſtem. Petals expanding in the evening, divided almoſt to the baſe; ſegments linear, obtuſe. Crown cloven, acute. Five of the ſtamens projecting, the other five ſhorter, faſtened to the petals. Styles pubeſcent varying in length. Capſule ovate. Seeds kidney-form, wrinkled [r].

Native of ſeveral parts of Europe, chiefly on limeſtone rocks: alſo of Barbary, on hills about Algiers. In England, it was firſt ſhewn to Mr. Ray by Thomas Williſel, on the walls of Nottingham caſtle and thereabout. Morton found it between Harringworth and Wakerly in Northamptonſhire. Mr. Woodward has ſince obſerved it on rocks in Dovedale, Derbyſhire. Archdeacon Pierſon, about Knareſborough, Yorkſhire. Mr. Pennant, near Gloddaeth in Caernarvonſhire. Mr. Mackay obſerved it in Scotland, in 1793, near North Queen's-ferry. It flowers in june and july.

12. Stems diffuſed, ſmoothiſh, aſcending. Branches divaricating, ſhorter. Leaves ſmooth above. Calyxes have ten purpliſh villoſe angles. Petals white, cloven half way. Diviſions of the nectary (or crown) bifid, patulous, with a white ſtreak. It is a perennial plant, native of Tartary [s].

The plant which ſome of our botaniſts took for this, and which Linneus made to be a variety of his *Cucubalus Behen*, is the *Lychnis maritima repens* of Caſp. Bauhin and Ray; and Silene maritima of Withering and Smith. See *n*. 14.

13. This has the habit of *nutans*, but is twice or thrice as large. The leaves are much narrower, linear-lanceolate and ſmooth. Calyx an inch long, more cloſely pubeſcent. Border of the petals obcordate (not cloven half way,) the ſegments widening and rounded; by no means divided to the baſe into linear ſegments, as in *nutans* [t].

This plant was long miſtaken for *Cucubalus viſcoſus* of Linneus; and lately was referred to *Silene nutans*. It is now aſcertained by Dr. Smith to be the *paradoxa* of Linneus and Jacquin. It cannot be the *Cucubalus dubrenſis* of Miller. See our *Cucubalus viſcoſus*.

Native of Italy, and of England on Dover cliffs, where it was found by Mr. Newton. Mr. Dillwyn (Linn. tranſ. 6.) affirms that *S. nutans* grows on the cliffs about Dover abundantly, and on Sandgate caſtle; but believes that *S. paradoxa* is not to be found in the neighbourhood.

14. Root perennial, creeping. Stems many, proſtrate, leafy, with the extremities only growing upright, and terminating in a handſome white flower, generally ſolitary, but ſometimes accompanied by one or two more; but the ſtem never bears ſo many flowers as in the common Spatling Poppy (*Cucubalus Behen* or *Silene inflata*,) neither is the capſule ſo long as in that. In the leaves and calyx there is a conſiderable affinity between them. The petals are conſtantly crowned at their baſe; a circumſtance which ſometimes though rarely occurs in the Spatling Poppy or Bladder Campion, from which this is clearly diſtinct: indeed few plants vary leſs in their habit, though in the number of its ſtyles and their correſponding fruit-cells it varies from three, the prevailing number, to four or five [u].

Stems ſmooth, procumbent, ſpreading. Flowering-branches aſcending, from ſix to twelve inches high. Leaves connate, lanceolate, ſmooth, one or two inches long, and one or two lines broad. Each branch bears on its ſummit from one to three flowers on ſhort fruitſtalks, much reſembling thoſe of *Cucubalus Behen*; but in this the reticulated veins of the calyx are deep purple. The petals are deeply cloven, with oval ſegments; beneath which are two prominent teeth forming the crown. Anthers deep purple [x].

The leaves vary much in breadth, thoſe on the barren and trailing branches being the narroweſt; the edges are tranſparent, ſerrate with very minute prickles. Peduncles either axillary or terminating; moſtly ſolitary, though in the larger and more upright plants

there

Digitized by Google

there are ſometimes three terminating flowers, as figured in Flora Danica. Floral leaves two, oppoſite, ſpear-ſhaped, at ſome diſtance from the flower. Calyx ſemi-tranſparent, with a net-work of veins, but neither hairy nor ribbed, often coloured. Petals white, cloven; ſegments rounded very entire; the crown formed by two little plaits in each petal. Styles ſometimes five. Germ oblong, mulberry-coloured. Seeds fixed on ſhort pedicels to the receptacle, which becomes looſe[f].

Native of Norway, Gothland and Britain. Common on many of our coaſts, as Southwold in Suffolk, Wells in Norfolk. Suſſex and almoſt all the ſouthern and weſtern coaſts: found by Johnſon in 1632 in the Iſle of Thanet oppoſite to Sandwich: Portreth near Hayle in Cornwall; on Cheſil bank, and at Weymouth, Swanage, Studland, Poole, and the north ſhore of Dorſetſhire. Cardiganſhire in Wales; and in Scotland.——Mr. Thomas Heſketh reported to Gerarde, that by the ſea ſide in Lancaſhire, at Lytham, five miles from Wigan, there is a variety with red flowers.

For *Silene inflata* or Bladder Campion ſee *Cucubalus Behen*, and for *Silene Otites* ſee *Cucubalus Otites*.]

15. Stem low, ſhrubby, dividing into ſeveral ſhort branches. Leaves ſmooth, ending in acute points. The flower-ſtalks riſe about a foot high, and divide into ſpreading panicles, ſuſtaining two and three flowers, of an herbaceous white colour. Capſules oval, ſmooth, having thick covers.

Native of Sicily [and Germany. Cultivated in the Edinburgh garden in 1683. It flowers in june and july[g].]

16. Root perennial (or biennial.) Lower leaves narrow, ſpear-ſhaped, ſmooth, gathered in cluſtered heads, from the middle of which riſes an erect clammy ſtem a foot and half high, with very narrow leaves on it. Flowers from the upper axils, on ſhort peduncles ſuſtaining two white flowers, having long tubes, and ſtanding erect. The flowers are cloſed during the day, but expand at night.

[It is a very ſmooth plant, with wand-like jointed ſtems, often decumbent at the baſe, even, round, ſingle at bottom, but looſely panicled at top. Leaves oppoſite, narrow-lanceolate, acuminate: lower ſtem-leaves decurrent, much longer than the internodes; upper ſhorter, ſeſſile. Bractes narrow-lanceolate, very ſharp. Peduncles one, two or three-flowered. Each flower pedicelled, nodding a little. Calyx ſmooth and even, tubular, often violet-coloured, five-toothed; teeth ovate, acute. Petals white above, pale violet beneath, cloven beyond the middle; ſegments narrowed at the baſe, blunt at the end: claws a little longer than the calyx, with two teeth at the top. Stamens projected. Capſule oblong on a long pedicel within the calyx. The ſtems are ſometimes green, ſometimes purple[a].

Native of Perſia and Mount Atlas. Cultivated by Mr. Miller in 1759.

17. Root perennial. Leaves lanceolate-linear, ſmooth. Stems panicled, ſmooth. Peduncles ſhorter than the calyx. Calyx ſubclavate, cut out at the baſe. Petals bifid with the ſegments divaricating.—Native of Hungary[b].]

18. Lower leaves obtuſe, and gathered in circular heads, like ſome of the Houſeleeks or the Auricula, ſmooth and of a pretty thick conſiſtence. Stems five or ſix feet high and viſcous. Leaves lanceolate, oppoſite. Flowers on ſhort peduncles from the axils in whorls; each peduncle ſuſtaining three or four greeniſh flowers. Capſules oval, ſpreading open at top, and filled with angular ſeeds.

[Leaves of the former year very large. Stem of the ſecond year two feet high, ſimple; the lower joints ſhort and villoſe; the upper very long, naked, viſcid. Lower leaves obovate, fleſhy, fragile, concave, pubeſcent, ſeſſile. Common peduncles oppoſite, ſpreading horizontally, very ſhort, dichotomous. Calyxes pubeſcent. Corollas green, with a very indiſtinct crown. The flowers open only by night.

[f] Withering. [a] Hort. kew. [c] Desfontaines. [b] Ehrhart and Roth.

Native of Africa[c]:—Mr. Miller ſays, of Sicily and Crete. Cultivated by him in 1759.

19. Root biennial. Stem two feet high, firm, hirſute; with alternate branches. Leaves orbiculate or obovate, very blunt, like thoſe of Purſlane, thick, fleſhy, hairy on both ſides. Raceme terminating, compoſed of from eight to twelve flowers, of a dull colour, with hirſute calyxes and ovate bractes. Petals emarginate, properly crowned. Piſtils three.

Native of the Cape of Good Hope[d]. Introduced in 1774, by Mr. Francis Maſſon. It flowers in july and auguſt[e].]

20. Lower leaves roundiſh and hollowed like a ſpoon: thoſe upon the ſtalks obtuſe, and ſtanding by pairs, threes or fours round the ſtalks; they are deep green, ſmooth and ſeſſile. Stalks round, ſmooth, from two to three feet high. Flowers in looſe ſpikes at the top, of a green colour.

[Root biennial. Plant a foot high and more. Stems erect, round, pubeſcent, thickening at the joints. Leaves lanceolate-ovate, pubeſcent, green, acute. Branches alternate. Panicle brachiate, with dichotomous few-flowered peduncles. Calyxes nodding, cylindrical, with ten angles, viſcid like the peduncles. Flowers greeniſh white, with the petals cloven half way; the lobes recurved and linear. Stamens the length of the tube. Piſtils the length of the petals[f].

Native of Spain, Portugal and Siberia.—Cultivated in 1739, by Mr. Miller. It flowers in june and july[g].]

21. Annual, with an upright branching ſtalk, a foot and half high, having ſwelling viſcous joints, with narrow, acute-pointed, ſmooth leaves, ſeſſile and near three inches long. Flowers terminating, ſmall and red. Capſules globular, ending in acute points, and with ſtriped calyxes over them.

[Plant pubeſcent. Stem dichotomous at top, with corymbed branches. Flowers erect, pedicelled. Calyx marked with thirty ſtreaks, and having five awl-ſhaped teeth; when young it is ovate-cylindrical, but when the fruit is ripe, it is inflated, large, globular, acuminate, cloſed. Petals ſmall, roſe-coloured. Capſule within the calyx, ſeſſile, ſhaped like the bottle gourd[h].]

Native of France, Spain and Italy, among corn. It flowers in june, and the ſeeds ripen in auguſt. [Cultivated by Mr. Miller in 1759.

22. Root annual, ſmall, ſomewhat branched. Stem erect, round, pubeſcent, leafy, dichotomous. Leaves linear-lanceolate, acute, quite entire; very ſoftly pubeſcent on both ſides, and of a grayiſh-green colour. Flowers from the divarications of the ſtem, ſolitary, pedicelled, erect, in an evening exhaling a ſweet ſmell approaching to that of a Honeyſuckle, but weaker. Calyx cylindrical, becoming conical as the fruit ſwells, membranous, with thirty green downy prominent equal ribs, and five ſharp teeth. Petals narrow; the border cloven, roſe-coloured, with a ſharp tooth on each ſide of the baſe, and a notched ſcale above, forming the crown. Capſule ovate. Seeds rough[i].

Native of Germany, France, Spain, Italy, the Levant, and Barbary.—In England, it is found only in Kent, on the ſand hills near Sandown caſtle, where it was found by Sherard and Rand; and oppoſite the Warren houſe at New Romney; found by the Rev. Mr. Stacey. It flowers in july.

Dr. Smith thinks it to be more than probable that *S. conoidea* is a very ſlight variety of this, with ſmoother leaves; the diviſion of the petals not being an invariable mark.

23. This has an upright, round, ſubvilloſe and rather glutinous ſimple ſtem, ſlightly dichotomous at the top, with but few flowers: leaves oblong-lanced, entire, oppoſite, ſeſſile, roughiſh and hairy: flowers on very ſhort footſtalks, opening by night; petals ſemibifid, roſe-coloured. It is an annual, riſing from a ſlender root[k].

24. This is an annual or biennial plant. Leaves five-nerved, petioled, rugged. Stem dichotomous,

Digitized by Google

pubeſcent downwards. The primary flower from the fork; the reſt ſpike-raceined ſolitary, directed one way, nodding. Calyx ten-angled, rugged. Petals bifid, crenate. Capſule erect[l].—Native of Hungary.

25. Plant annual, rough-haired all over, not viſcid, half a foot high. Stem branched, erect; the branches moſtly alternate. Lower leaves ovate; upper lanceolate, quite entire, ſeſſile, oppoſite. Raceme bifid, with one pedicelled flower in the fork, and three or four alternate on each branchlet ſhortly pedicelled, ſupported by two linear leaves, fleſh-coloured, opening in the evening. The raceme is alſo frequently ſimple. Calyx oblong, ſomewhat club-ſhaped, hairy, with ten green ſtreaks. Capſule ovate, ſubtrigonal, within the calyx on a long pedicel, opening by a ſix-toothed mouth. Seeds ſmall, kidney-form, grooved at the back.

26. This differs from *Cucubalus Behen* in having a crown to the corolla; the laminæ of the petals ſcarcely a third of the length of the calyx; the root annual; the corollas purpliſh, with white anthers; the calyx obtuſe; the flowers nodding, on a peduncle from the fork, ſhorter than the flower.

Native of the iſland of Candia or Crete[m]. Cultivated by Sherard in 1732.

27. Plant annual. Flowers erect, ſubſeſſile or on very ſhort peduncles. Leaves lanceolate, hairy-viſcid. Native of Spain and Toulouſe[n].]

28. Plant annual, from whoſe root come out ſeveral branching ſtalks, near a foot and half long, which trail upon the ground, oppoſite. Leaves oval, acute-pointed. The flowers come out ſingly from the axils, upon ſhort peduncles; they are large, and of a bright red colour, reſembling thoſe of the common wild red Campion. Capſules large, in inflated calyxes, having ten rough angles, containing many large roundiſh ſeeds, the weight of which cauſes the capſules to hang down.

[Native of Sicily and Crete or Candia. Cultivated in 1732 by James Sherard, M. D. It flowers in may and june[o].

29. A perennial ſpecies, of a weak or tender appearance and very ſmooth: ſtalks very numerous, procumbent, round, ſlender, and about two feet long, ſpreading in all directions, furniſhed with pretty numerous joints, from each of which proceeds a branchlet: leaves narrow, acute, ſmooth, but rough on the edges; thoſe on the firſt branches larger than the others: flowers ſolitary, upright, riſing from the diviſions of the ſtems and the tops of the branchlets; calyx purple-green with ten prominent lines: corolla purpliſh white, marked beneath with purple veins[p].

30. Root annual, ſmall in proportion to the herb, which often becomes very luxuriant in a manured ſoil. The whole plant is hairy. Stem erect, round, leafy, ſpreading, branched, dichotomous in the upper part. Leaves lanceolate, acute, ſoft and downy, deep green, ſeſſile; the lower ones obovate. Flowers few, ſolitary at the forks, erect on hairy viſcid peduncles, which are ſhort at firſt, but are afterwards lengthened out to about an inch. Calyx hairy, viſcid, white, with ten green branching veins, and linear teeth almoſt the length of the tube. Petals cloven half way, crowned with obtuſe toothlets at the throat, of a cream colour tinged with red, the border rolled in during the day, but unfolding in the evening, and then the flowers become very ſweet-ſcented, at leaſt while warm weather continues[q]. Capſule clothed with the calyx marked with alternate branching veins, ovate-conical, one-celled at top, three-celled below, opening in ſix parts: partitions membranaceous, very thin, very ſhort, at the upper wall of the capſule ending in mere raiſed ſtreaks. Receptacle columnar, free above, hiſpid, thick, longer than half the capſule. Seeds very numerous (150) kidney-form globular, flattiſh on the back, rugged with acuminate tubercles in rows, yellowiſh ruſt-coloured[r].

Native of Sweden, Germany, Switzerland, Dauphiné, Piedmont, England, in ſandy fields. In the midland, eaſtern and ſouthern counties. In Norfolk and Suffolk not uncommon; eſpecially on the weſt ſide of Norwich. In Cambridgeſhire, found by Dale by the road from Newmarket to Canvaſs-hall in Wood Ditton; by Relhan, near the turnpike on Newmarket heath, near Catlidge-hall, between Snailwell and Chippenham, and between Chippenham-park wall and the gravel-pit. In Bedfordſhire, Oakley weſtfield, by Dr. Abbot. In Oxfordſhire, Headington, Cowley, Stanton Harcourt and South Leigh, by Dr. Sibthorp. Near Wetherby, in great abundance, by Sir Thomas Frankland. It flowers in july.

31. This is a biennial plant, with dark red flowers, ſomewhat like that of the Clove Pink, in which the beauty of this plant chiefly conſiſts; for the plant itſelf is of rude growth. It grows readily, riſing to the height of about two feet, blows freely during moſt of the ſummer months, and ripens its ſeeds[s].—Native of the Cape of Good Hope. Introduced by Mr. Maſſon in 1775. It flowers from may to ſeptember.

32. Biennial. Native of the Cape. Introduced with the preceding at the ſame time by Mr. Maſſon. It flowers in auguſt[t].

33. Plant perennial, polymorphous. Flowers as in *Lychnis dioica* white and deep red. Calyxes narrower than its congeners, hirſute. The ſtamens with the ſtyles prominent beyond the flower. Stem ſometimes ſimple, a finger's length, terminated by flowers collected into a bundle; ſometimes a foot high, trichotomous at the end, with a middle peduncle always one-flowered. Leaves oblong or broad-lanceolate, as in *Gomphrena globoſa*.—Native of Virginia[u].

34. Root annual, ſlender, fibrous. Stems round, ſmooth, viſcid at the joints, dichotomous, the laſt diviſion trifid, with a ſingle flower between. Peduncles long and ſlender. Flowers open during the night, crowned at the throat. Calyxes ten-ſtreaked, and divided at the end into five ſhort purpliſh ſegments. Capſules obſcurely three-ſided, three-celled.—Native of Virginia and Carolina[x]. Cultivated in 1732, by James Sherard, M. D. It flowers in june and july[y].

35. Root annual: ſtem branching, diffuſe, about half a foot in length, with villoſe dichotomous branches: leaves oppoſite, ſeſſile, ſubcuneiform, rather obtuſe, perfectly entire, ſomewhat fleſhy, and very ſlightly muricated on the edges; they are about an inch in length: flowers ſmall, upright, on ſolitary footſtalks of about half an inch long, riſing from the boſoms and tops of the branches: calyx tubular, and thickly covered with headed hairs: petals rather longer than the calyx, fleſh-coloured above, and white beneath.—Native country uncertain[z].

36. This is an annual plant, differing from all the ſpecies of Silene in the flowers being clandeſtine from the defect of petals. The whole is pubeſcent. Stem round, ſix inches high, with the branches ſimple and oppoſite. Lower leaves obovate-lanceolate, upper lanceolate, uppermoſt linear. Peduncles ſolitary in the forks of the ſtem, the length of the calyx. Calyx erect, oblong-ovate, ten-ſtreaked. Capſule ſhortly pedicelled[a].

37. Root annual, ſimple, fibrous, deſcending ſtraight down. Sometimes the ſtem is ſimple and upright. Sometimes there are ſeveral ſtems decumbent at bottom, with three or four joints in the lower part from an inch to two inches diſtant from each other, and only one joint on the upper part a hand or more in length, before the ſtem divides into branchlets and peduncles. Root-leaves oblong; upper ones narrower, reſembling thoſe of *Antirrhinum* or Snapdragon. Flowers ſmall, with reddiſh cloven petals, and a ſcarcely perceptible crown. Pedicels at firſt ſhort, but lengthening as the capſules advance to maturity. Calyxes ſwelling, ten-ſtreaked, five ſtreaks longer, and five ſhorter. The joints are viſcid, but very ſparingly. It flowers in may[b].

Native of Portugal and the Levant. Cultivated in the Eltham garden in 1732.

[l] Ehrhart. [m] Linn. ſpec. [n] Linn. amoen. [o] Hort. kew. [p] Murray. [q] Smith brit. & engl. bot. [r] Gærtner. [s] Curtis. [t] Hort. kew. [u] Linn. ſpec. [x] Dillenius. [y] Hort. kew. [z] Jacquin. [a] Willdenow. [b] Dillenius.

Digitized by Google

[38. Root annual, fibrous. Stem from a foot to a foot and half in height, ſlender but firm and erect, round, ſmooth, green, putting out many branches from the very bottom. Leaves from the joints glaucous, ſmooth; the lower ones wider, bent back, thoſe at the middle, joints narrower, leſs bent back; the upper ones ſhorter and narrower, upright or but little bent back. Flowers frequent on the branches, on pedicels as fine as a hair, never opening, whitiſh within, obſoletely ochre-coloured on the outſide: petals five, narrow, cloven, not crowned. Capſule of an oblong round form, three-celled, opening at top into ſix parts. Calyx cylindrical, five-toothed. Stems and branchlets somewhat viſcid to the middle of the internodes [c]. According to Linneus, the corolla has no border, and there are frequently only five ſtamens. Dillenius ſays that there are ten ſtamens concealed within the corolla, having ſmall whitiſh anthers. It flowers in july and auguſt.

Native of the South of Europe according to Linneus. Allioni ſpecifies the county of Nice, and Scopoli, Carniola. The Kew catalogue makes it indigenous of Madeira.—Cultivated in 1732, by James Sherard, M. D.[d]

39. This is an annual plant, reſembling the preceding, but differing from it in having an angular calyx, a border to the corolla, and ciliate leaves.—Native of the Cape of Good Hope [e].

40. This alſo is an annual plant with the habit of *S. inaperta*; but the leaves are narrower, and the calyxes ſtreaked longitudinally. The plant is a ſpan high, brachiate and dichotomous. Leaves linear, acute, ſmooth. Peduncles filiform, very narrow, long, erect, from the forks, one-flowered. Calyxes club-ſhaped, long, purpliſh, with alternate white ſtreaks. Stamens almoſt the length of the corolla. It may perhaps be only a variety of *S. inaperta* [f].—Native of Portugal. Cultivated in 1759, by Mr. Miller. It flowers in july and auguſt [g].

41. Stem dichotomous-panicled, ſpreading, filiform, with the joints viſcid. Calyxes ſmooth. Flowers bright purple, with the petals cloven half way, from upright ſpreading a little [h].

Stems from a foot to two feet and more in height, round, ſmooth and ſomewhat glaucous, viſcid at the joints, dividing about the middle into ſlender branches, at the top of which, on long ſlender peduncles, are middle-ſized flowers, without ſcent, expanding only in the day-time, crowned. Capſules ſwelling in the middle, narrowed towards the top. Calyxes deeply ſtriated, and when the capſules ſwell, the ſtreaks become ribs. The lower leaves are like thoſe of the Daiſy and ſubhirſute; the next are narrower and leſs hairy; thoſe at the upper joints are quite ſmooth and ſomewhat glaucous, as in the Pink [i].

Native of Crete or Candia. Cultivated in 1732, by James Sherard, M. D. It flowers from june to auguſt [k]. Dillenius ſays in may; and mentions a variety, which is higher, with a ſhorter and more ſwelling calyx, and a capſule ſomewhat more turgid eſpecially at the baſe, that flowers a fortnight earlier than the other.]

42. Root biennial. Stalk round, clammy, a foot and half high, having ſwelling joints. Leaves narrow and ſmooth, growing round the ſtalk in cluſters. The upper part of the ſtalk divides into ſpreading branches by pairs, and has red flowers coming out ſingly from the axils, and ſeſſile. Capſules oblong, viſcous, filled with angular ſeeds.

[Root annual. Stem upright, round, ſmooth, thickiſh, with ſtiff branches. Leaves very ſmooth, broad-lanceolate, quite entire, longer than the internodes; the lower running down into the petiole and blunt, the middle and upper attenuated to both ends and ſeſſile: the branch-leaves narrow-lanceolate. Flowering-branches dichotomous. Flowers ſubſeſſile in the forks. Bractes awl-ſhaped, ſome of them often longer than the flower. Calyx tubular, membranaceous, five-toothed, when the fruit is ripe ovate, five-cornered, narrowed at the baſe. Corolla ſmall, of a deep roſe-colour, a little longer than the calyx; the border of each petal emarginate. Capſule ovate-conical, ſhortly pedicelled, length of the calyx, opening at top in five parts, three-celled. Seeds rufous, ſmall, kidney-form, wrinkled. The plant is extremely viſcid [l].—Native of the South of France, Spain, Siberia and Algiers.

The ſlimineſs of this plant is ſuch, ſays Gerarde, that if you take it in your hands, your fingers will cleave together, as if your hand touched bird-lime; and if flies do light upon the ſame, they will be ſo intangled with the limineſs, that they cannot fly away. Whereupon I have called it *Catch-flie* or *Limewort*. We have theſe plants in our London gardens, rather for toys of pleaſure, than any vertues they are poſſeſſed with.

43. Root perennial. Stems branching and frequently lying on the ground. Flowers ſmall, whitiſh with a tinge of Carnation, and greeniſh beneath, often incloſed in a calyx with ten cylindrical ſtreaks [m].

Native of Dauphiné, Hungary, Auſtria, and Bohemia.]

44. This is an annual plant with erect ſtalks, a foot and half high, for more than an inch below each joint very glutinous. Lower leaves broad, oblong, ſmooth, ſeſſile. Flowers in terminating bunches, ſtanding erect, and forming a kind of umbel. Capſules ſlender, oblong, filled with angular ſeeds.

[Root ſmall, ſtem branched, leafy, ſmooth. Leaves embracing, ovate, glaucous, ſmooth. Panicles terminating, leafleſs, many-flowered, dichotomous, faſtigiate with little bractes. Flowers erect. Calyx clavate-linear, ten-angled, very ſmooth and even, glaucous, with ſmall, rounded, purpliſh teeth. Petals rounded, emarginate, acutely crowned. Capſule elliptic, pedicelled [n].

Native of Denmark, Germany, France, Switzerland, Carniola, Piedmont. England, obſerved on the banks of the river half a mile below Cheſter, by Dr. Richardſon. It flowers in july and auguſt. This plant is not properly indigenous of our iſland, but, as Miller obſerves,] having been many years cultivated in our gardens, the ſeeds have ſpread upon walls, buildings, &c. ſo far, as to induce ſome to believe it a native.

There are three varieties which generally retain their differences: one has a bright purple flower; the ſecond a pale red; and the third a white flower.

[45. Root annual. Stem erect, dichotomous, ſomewhat viſcid above, branched below. Leaves oleraceous, the lower glandular-ciliate, the upper ſeſſile. Flowers terminating, dichotomous, in bundles, faſtigiate. Calyx erect, club-ſhaped. Corolla bright purple, with a white band, crowned at the throat. Petals ovate, bifid, with a more ſlender tooth or ſegment at the baſe of the border on each ſide [o].

Native of the Levant. Introduced in 1781, by P. M. A. Brouſſonet, M. D. It flowers in may and june [p].

46. Stem herbaceous, a palm high, brachiate, very ſlightly tomentoſe. Leaves obovate, narrowed at the baſe, ſcarcely fleſhy, even, ſharpiſh. Flowers terminating, one or two, peduncled, erect. Calyx club-ſhaped, ſubpubeſcent, with ſhort teeth. Petals obcordate or emarginate, obtuſe, fleſh coloured, ſhorter than the calyx, with a ſharp tooth on each ſide, and therefore four-cleft. The coronet is very ſhort, obtuſe and emarginate. The ten ſtamens are in the throat; and the three ſtyles oblique.——Native of Egypt [q].

47. Petals deeply bifid with a tooth on each ſide.—Native of Carolina [r].

48. Root fibrous, perennial. Stems many, forming a tuft, filiform, a finger's length and half. Leaves oppoſite, ſeſſile, ovate, acuminate, reſembling thoſe of common Chickweed, but ſlightly ſinuate and very finely villoſe: the firſt pair is ſmaller, the next wider,

Digitized by Google

the uppermoſt more acuminate and again ſmaller; often five pairs in the whole. The ſtem ends in a ſhort peduncle, bearing a ſingle flower, ſometimes accompanied with one on each ſide, whitiſh tinged with roſe-colour, and yellowiſh on the outſide. Petals half-five-cleft, the ſegments linear-roundiſh, with a deeply bifid crown. Calyx inflated, pale green, except towards the ſun where it is reddiſh, ten-angled with the angles alternately larger and ſmaller, five-toothed. Capſule oblong, one-celled, opening by four two-toothed valves, not revolute. The plant is viſcid all over.

Native of the higher rocks of Piedmont, the county of Nice and the Col de Tende [a].

49. Root probably perennial. Stems very many, a foot high, erect, dichotomous, round, ſmooth. Leaves oppoſite, naked, ſomewhat fleſhy, mucronate, rugged at the edge. Peduncles long, viſcid in the middle. Flowers erect, very large. Calyx ten-ſtreaked, curved in a little, five-cleft at the mouth; the teeth acute membranaceous at the edge. Claws of the petals longer than the calyx; borders cordate, patulous, with a bifid, upright crown. Five of the ſtamens the length of the corolla, and five ſhorter. Anthers linear, emarginate. Germ obconical. Styles longer than the ſtamens. Stigmas revolute, pubeſcent. Capſule erect, ovate, ſhining, three-celled, opening irregularly.

Native of Armenia, where it was found by Tournefort [c].

50. Root perennial. Stems a ſpan high, erect, even. Flowers in a dichotomous panicle. Calyx even, with blunt teeth. Petals four-cleft, white, the length of the calyx. Capſule longer than the calyx.

Native of the mountains of Auſtria [a]. Introduced in 1774, by Joſeph Nicolas de Jacquin, M. D. It flowers from may to july [e].

51. This is a little plant which ſpreads and branches out dichotomouſly. Leaves oval, ſeſſile, ſmooth, entire, glaucous. Flowers ſmall, funnel-ſhaped; petals ſlightly emarginate, or only truncate, white. It is biennial. The crown is ſcarcely apparent; and the hollow or funnel ſhape of the calyx and corolla diſtinguiſhes this ſpecies [f].

According to Haller, the root is large, woody and rugged; the ſtems erect, very much branched and brachiate; the leaves glaucous, ſmooth, and ovate-lanceolate; the flowers terminating, on long peduncles, ſolitary, forming all together a looſe umbel; the calyx bell-ſhaped, inverſely conical, marked with lines; the petals milk-white, emarginate, cordate, with earlets forming a coronet. Fruit conical.

Native of Lapland, Sweden, Germany, Dauphiné, Piedmont, Siberia. Introduced in 1771, by Monſ. Richard. It flowers from june to auguſt [a].

52. Root woody, branched. Stems ſeveral, a finger's length, ſmooth. Leaves oppoſite, linear, acute, from four to ſix pairs. Peduncle terminating, filiform, length of the ſtem: ſometimes but ſeldom there is a ſecond lateral peduncle. Flowers ſolitary. Calyx club-ſhaped, ſmooth. Border of the petals ſhorter than the calyx, red beneath [a].

It is a creeping plant, with the branches commonly ſimple, and viſcid. Petals pale red, rolled inwards, within an oblong, reddiſh calyx, a little channelled and viſcid [b].

Native of France, Italy, Carniola and Japan. Introduced in 1772, by Monſ. Richard. It flowers from june to auguſt [c].]

53. This plant ſeldom riſes more than ſix inches high, ſending out many ſhrubby decumbent branches. The flowers grow erect, are of a pale red colour, and are ſucceeded by turgid capſules, filled with roundiſh ſeeds.

[Stems a hand in length, filiform, woody. Leaves wider towards the end, acute, glutinous, oppoſite in cluſters. Peduncle terminating, ſolitary, one-flowered, length of the flower. Flower erect: petals bifid, with a ſmall crown: calyx club-ſhaped, with ten raiſed browniſh ſtreaks, and ſmall blunt teeth. When the flowering is paſt, it increaſes three times in ſize; is club-ſhaped, ſcarioſe, and inflated as in Behen [d].

Root hard, woody, perennial. Stems one-flowered or dichotomous and three-flowered. Leaves linear-elliptic, acuminate, ſeſſile, hairy-viſcid. Calyx inflated, at firſt cylindrical, then oval, an inch long, five-toothed, ten-ſtreaked, viſcid-hairy, netted with purple veins. Petals quadrangular cordate, within white, very pale roſe-coloured, or whitiſh, on the outſide purple with red veins; the border often rolled back towards the centre of the flower: ten ſcales of the ſame colour form an internal corolla, and the petals have a wing on each ſide. Capſule three-celled, cloven into five or ſix parts at the top.

Native of the higher alps of the Vaudois, the Valais and Dauphiné. Cultivated in 1768, by Mr. Miller. It flowers from june to auguſt [e].

54. Root perennial. Root-leaves heaped into a tuft, linear, blunt, even. Stems quite ſimple, very ſhort, often three-jointed. Calyx oblong, bell-ſhaped, ſpreading, blunt, pubeſcent, length of the ſtem.

Native of the mountains of Italy, Moravia and Carinthia [f].

55. The root is perennial, forms a thick tuft, and deſcends far in the earth. Leaves heaped, ſheathing, ſpreading, ſlightly keeled. Peduncles terminating, erect, naked, indiſtinctly quadrangular, ſmooth, lengthening out after flowering (to two inches.) Flowers erect, pretty, roſe-coloured (or bright purple.) Calyx bell-ſhaped, half-five-cleft, five-ribbed, ſmooth. Petals ſlightly emarginate, crowned. Capſule cylindrical, double the length of the calyx [g].

Leaves awl-ſhaped, ſmooth, ſet at the edges with hooked teeth pointing downwards. Petals cordate, with two ſmall teeth forming a coronet. Capſule ſmooth and ſhining, tinged with purple [h].

Linneus remarks that the herb reſembles a *Bryum*.

Native of the mountains of Lapland, Denmark, Britain, Germany, Dauphiné, Auſtria, Piedmont, Switzerland and the Pyrenees. On the higheſt mountains of Devonſhire, Wales and Scotland. Dartmoor; Caernarvonſhire near Llanberys; Ben Lomond, &c. Iſles of Mull, Rum and Skye. It flowers from may to july.

56. Stem ſimple or ſparingly branched, hairy. Leaves alſo hairy: the lower ſpatulate, obtuſe, running down the petiole; middle and upper ſtem-leaves lanceolate, acute, ſeſſile. Flowers ſubſeſſile, erect. Bractes lanceolate-ſubulate, twice or three times ſhorter than the calyx. Calyx tubular, ſtriated, five-toothed; when the fruit is ripe ovate, narrowed at the baſe. Capſule ovate, ſmooth, pedicelled, erect, three-celled, many-ſeeded. Annual.—Native of Mount Atlas.

57. Stem erect, with ſlender rod-like branches. Leaves villoſe; lower obtuſe, upper narrow, lanceolate, acute. Flowers ſeſſile or on very ſhort pedicels, ſolitary, preſſed cloſe, a little longer than the internodes, except the lower ones. Bractes ſmall, awl-ſhaped. Calyx tubular, ſmooth, ten-ſtreaked, five-toothed. Petals white, bifid. Capſule ſmooth, ovate-oblong, pedicelled within the calyx. Annual.—Native of Barbary, in fields near Maſcar.

58. Stem erect, hairy, branched. Branches ſlender, erect. Leaves hairy: root-leaves ſpatulate or obovate; lower and middle ſtem-leaves narrow-lanceolate. Flowers in looſe racemes, alternate, ſeſſile or ſubſeſſile, axillary; the lower ſhorter than its linear-ſubulate leaflet. Calyx hirſute, tubular, ten-ſtreaked, erect, when the fruit is ripe ovate-round, five-toothed; teeth longiſh ſubulate. Capſule even, ovate, acuminate, opening at top, ſubſeſſile within the calyx. Petals roſe-coloured, a little longer than the calyx, for the moſt part three-toothed. Annual.—Found in corn fields near Algiers, by Desfontaines; and in Spain by Cluſius, flowering in may.

59. Stem erect, ſmooth, branched, viſcid, ſlender.

Leaves

Digitized by Google

Leaves very ſmooth, acute. Flowers panicled. Peduncles filiform, one, two or three-flowered; the middle flower ſeſſile or on a ſhort pedicel. At the baſe of the pedicels are two awl-ſhaped leaflets. Calyx thin, club-ſhaped, very ſlightly ten-ſtreaked, netted with purpliſh veins, five-toothed: teeth ovate, acute. Corolla ſmall, roſe-coloured: border of the petals linear, narrow, emarginate, with a ſlender claw, the length of the calyx, having two appendicles at the top. Capſule ſmooth, ovate-oblong, on a long pedicel, ſcarcely ſurpaſſing the calyx, opening at the top, three-celled. Seeds many, ſmall, brown, kidney-form, wrinkled, inſerted into a central, elongated, branched receptacle.—Native of Algiers.

60. Stem pubeſcent, jointed, erect or elſe decumbent at the baſe, branched. Branches ſimple or forked at top. Flower ſolitary in each fork. Leaves oppoſite; lower pubeſcent, ſpatulate, blunt, decurrent into a ciliate petiole; middle and upper leaves lanceolate, ſeſſile. Flowers on ſhort pedicels, nodding a little. Bractes ovate-lanceolate. Calyx round, narrowed at bottom, membranaceous, ten-grooved, five-toothed; when the fruit is ripe ovate, contracted at the baſe. Petals roſe-coloured: border deeply two-parted; ſegments narrow, diſtinct, oblique, obtuſe, with two appendicles at the top of the claw, forming the coronet. Capſules ovate, ſmooth, erect, pedicelled, from five to ſeven-valved at top, three-celled. Seeds many, brown, kidney-form. This is a very handſome ſpecies, flowering during ſpring in the fields of Sbiba in Barbary. Annual.

Brouſſonet found a variety in Morocco, which was ſmaller, and had villoſe calyxes.

61. Stems often many from the ſame tuft, branched, erect, hairy, ſeldom ſmooth. Leaves oppoſite; lower obovate, decurrent, ciliate at the baſe; middle and upper ſtem-leaves ſeſſile or ſubſeſſile, ovate, often acuminate. Flowers one, two or three from one peduncle. Peduncles villoſe. Calyx tubular, round, ſlender, pubeſcent; when the fruit is ripe widening from the middle to the top, five-toothed; teeth acute. Petals roſe-coloured, blunt: claws a little longer than the calyx, with two appendicles at the top. Capſule ovate, opening at top, three-celled. It has very much the appearance of Jacquin's *S. Atocion*, (Orchidea, n. 45.) but differs in having the petals quite entire. Perhaps it may be a variety, Annual.—Native of Mount Atlas.

62. This is a viſcid plant covered with very ſhort villoſe hairs, and for the moſt part covered with ſand and duſt. Stem erect, very much branched; the branches panicled. Flowers very numerous. Peduncles axillary, unequal. Pedicels erect. Calyx ten-ſtreaked, ovate, five-toothed; teeth ſmall, acute. Petals white, ſmall. Capſule ſmooth, even, ovate, very ſhortly pedicelled within the calyx, five-valved at the top. Perennial on ſand by the coaſt of Barbary.

63. This alſo is a villoſe glutinous plant, covered with ſand. Stems procumbent at the baſe, jointed, branched. Branches alternate, ſtriated. Leaves like thoſe of *Ceraſtium vulgatum*, thickiſh, villoſe; root-leaves ſpatulate; ſtem-leaves linear-lanceolate, obtuſe. Flowers axillary and terminating, ſolitary or in pairs, pedicelled. Calyx tubular, when the fruit is ripe ovate, pubeſcent, ten-ſtreaked, five-toothed; teeth acute. Petals ſmall, white, bifid. Capſule ovate, ſmooth, five or ſix-valved at the top, pedicelled within the calyx. Allied to *S. ramoſiſſima*; but differs in having much fewer branches, the lower leaves with longer hairs, the ſtem decumbent at the baſe, flowers fewer, and the capſules pedicelled within the calyx. Perennial.—Native of ſandy ſhores of the Mediterranean ſea.

64. Stems from the ſame tuft many, erect or decumbent at the baſe, ſlender, pubeſcent, ſimple or ſparingly branched. Lower leaves a little narrower towards the baſe, bluntiſh; upper ſtem-leaves awl-ſhaped, connate, ciliate below. Peduncles lateral and terminating. Calyx purpliſh, tubular, when the fruit is ripe ſubovate, narrowed at the baſe, five-toothed; teeth ſmall, ovate, obtuſe. Claws of the petals a little longer than the calyx. Capſule even, ſhortly pedicelled within the calyx, five-valved, opening at top, three-celled.—Native of Barbary in fields.

65. This has the appearance of *S. nocturna*. Stem pubeſcent with a very ſhort pile. Lower leaves ſeſſile; upper lanceolate, remote. Flowering branches often forked. Lower flowers in threes; upper ſolitary. Calyx round; when the fruit is ripe ovate, narrowed below, five-toothed; teeth ſmall, acute, ſilky. Petals a little longer than the calyx, white; ſegments narrow, linear. Capſule ovate, pedicelled within the calyx. Flower in the fork, ſolitary, ſhortly pedicelled.—Native of fields about Algiers.

66. Leaves pubeſcent with a very ſhort pile: lower obovate, running down into a long petiole; middle and upper ſtem-leaves remote, narrow-lanceolate. Stem erect, pubeſcent below, branched. Branches oppoſite, panicled, ſpreading, viſcid, often bifid or trifid. Flowers on each peduncle one, two or more commonly three, the middle one on a ſhorter pedicel. At the baſe of the calyx two ovoid acute little bractes. Calyx tubular, narrower below, ten-ſtreaked, ſmooth or ſcarcely pubeſcent, when the fruit is ripe from the middle to the point widened, ovate, five-toothed; teeth ſmall, ovate, erect. Corolla white, the ſize of *Lychnis dioica*: claws a little longer than the calyx, with two teeth at top forming the coronet. Capſule ovate, pedicelled within the calyx, opening at top, three-celled. The flowers open at ſunſet and then ſmell very pleaſantly. Perennial.—Native of Barbary, in fields[1].]

PROPAGATION AND CULTURE.

Many of theſe plants are hardy annuals, which riſe eaſily from ſeeds ſown in the autumn, or ſpontaneouſly from ſcattered ſeeds.

3. Sow the ſeeds thin upon a border of light earth in autumn; and in the ſpring thin the plants to the diſtance of four inches, and keep them clean from weeds. They will flower in may and june. If ſome ſeeds be ſown in the ſpring, the plants will flower a month later. Theſe directions will ſerve for ſeveral other ſpecies.

2, 4, 5, 6, 21, 33, 34, 38, 40, 41, 45, &c. Sow the ſeeds upon a warm border in the autumn.

15. This may be increaſed by ſlips planted in a ſhady border: and if the plants are ſet in a warm dry border, they will live ſeveral years without ſhelter, but in moiſt ground they frequently rot in winter. This alſo riſes eaſily from ſeeds.

16. As the ſeeds ſeldom ripen here, it is difficult to propagate this ſpecies. The only way is to ſlip off the heads in june, and plant them under a glaſs; theſe will take root, if ſhaded from the ſun and duly watered.

18, 19, 20. Sow the ſeeds in autumn upon a warm border. When the plants are fit to remove ſet them on a dry ſoil in a warm ſituation, where they will live through the winter, and the following ſummer they will flower and ripen their ſeeds and then decay.

1, 28, 30, 44, &c. Permit the ſeeds to ſcatter, and the plants will come up without farther care.

[31, 32. Theſe require the protection of a dry ſtove, greenhouſe or glaſs-caſe. They may eaſily be raiſed from ſeeds, but are more commonly increaſed from cuttings, which ſtrike freely.]

42. Sow the ſeeds in autumn. When the plants are fit to remove tranſplant them into a bed of freſh earth at ſix inches diſtance, ſhading and watering them until they have taken new root. Keep them clean from weeds till autumn, and then tranſplant them to the places where they are deſigned to remain for flowering. When the ſeeds happen to ſcatter upon a wall, the plants will continue much longer than in the ground.

[50, 51, 52, 53. Theſe are perennial ſpecies, and may be propagated by ſeeds or cuttings. They are all hardy.] The ſeeds of the laſt ſhould be ſown in dry rubbiſh, where the plants will live many years; but in rich moiſt ſoils they rarely live through the winter.

[SILK COTTON. See *Bombax.*]
SILPHIUM (*of Pliny.* Σιλφιον *of Dioſcorides.*)
Lin. gen. n. 986. *Reich. n.* 1069. *Schreb. n.* 1334. *Gærtn. t.* 171. *Juſſ.* 188. Aſteriſcus. *Dill. elth.* 39. 42.
Claſſ. 19. 4. Syngeneſia Polygamia, Neceſſaria.
Nat. order of *Compoſitæ Oppoſitifoliæ. Corymbiferæ,* Juſſ.

GENERIC CHARACTER.

CAL. *Common* ovate, imbricate, ſquarroſe: *ſcales* ovate-oblong, bent back in the middle, prominent every way, permanent.
COR. *Compound* radiate. *Corollets* hermaphrodite in the diſk many: females in the ray fewer.
Proper of the hermaphrodites one-petalled, funnel-form, five-toothed; the tube ſcarcely narrower than the border:—of the females lanceolate, very long, often three-toothed.
STAM. in the hermaphrodites: *Filaments* five, capillary, very ſhort. *Anther* cylindrical, tubular.
PIST. in the hermaphrodites: *Germ* round, very ſlender. *Style* filiform, very long, villoſe. *Stigma* ſimple:—in the females, *Germ* obcordate. *Style* ſimple, ſhort. *Stigmas* two, briſtle-ſhaped, length of the ſtyle.
PER. none. *Calyx* unchanged.
SEEDS in the hermaphrodites none:—in the females ſolitary, ſubmembranaceous, obcordate, with the edge membranaceous, two-horned, emarginate.
REC. chaffy: *chaffs* linear.

ESSENTIAL CHARACTER.

Cal. ſquarroſe. *Seed-down* margined-two-horned. *Recept.* chaffy.

SPECIES.

[1. Silphium laciniatum. *Jagged-leaved Silphium.*

Corona ſolis americana arboreſcens, flore parvo luteo, ſemine alato. *Houſt. Mſs.*
Leaves lanceolate alternate rugged ſlightly ſerrate, ſtem ſhrubby.

DESCRIPTIONS, *&c.*

[1. Root perennial. Stem twice the height of a man, as thick as the thumb, quite ſimple, ſmooth below, above rugged with brown tubercles and white ſpreading hairs, round. Leaves petioled, two feet in length and a foot in breadth, embracing at the baſe, pinnatifid; ſegments on each ſide four or five, diſtant, narrow, tooth-ſinuate, rugged, with very ſolid ribs raiſed on both ſides; margin of the upper leaves purpliſh. Calyx of ten ſcales, ending in large awl-ſhaped ſpines. Petals of the ray thirty, length of the calyx, with a bifid ſlender ſtyle. Florets of the diſk yellow, many, ſeparated by chaffs, attenuated at the baſe; with a ſimple ſtyle. Seeds in the ray membranaceous, oval, emarginate, with two ſmall awns:—in the diſk columnar, four-cornered, abortive [k].
Native of North America. Introduced in 1781 by Monſ. Thouin. It flowers from july to ſeptember [l].
2. Stems two or three in number, ſtrong, upright, annual, ſmooth: panicled above, but without any branches throughout the whole length, being beſet with diſtant leaves: radical and lower cauline leaves large, heart-ſhaped, upright, rough, ſharply toothed on the edges, and ciliated with very ſhort hairs: they are very veiny, but not wrinkled: the footſtalks are long and embrace the ſtem at their baſe: the ſtem-leaves are ſimilar, but ſcarcely hearted at the baſe, and the others are more oblong, and half embrace the ſtem: the peduncles are elongated, round, and moſtly leafleſs; though a few of them are furniſhed with two oppoſite leaflets: the terminal flower on the ſtem flowers firſt, and when this begins to ſeed the lateral peduncles of the panicle begin to extend and proceed to flower. The ſmell of the flower, which is moderately large, and yellow, is ſimilar to that of the Sun-flower [m]. Calyx ventricoſe at the baſe, ſquarroſe above. Chaffs of the diſk almoſt the length of the barren flowers:—of the ray ovate-oblong, flat, a little ſhorter than the ſeed, to the baſe of which they are faſtened. Seeds ovate-rounded, plano-convex, very much compreſſed, pedicelled with a ſetaceous baſe, ſimply emarginate at top, without any viſible ſeed-down [n].
Native of North America. Introduced in 1756, by Meſſrs. Kennedy and Lee. It flowers in auguſt and ſeptember [o].
3. Root perennial. Stem higher than a man, four-cornered, even. Leaves oppoſite, ovate or deltoid, ſerrate, decurrent along the petioles, and oppoſitely perfoliate. Upper leaves ſeſſile, very wide, perfoliate. Peduncle terminating and from the axil of the laſt leaves, round, inclined. Calyx ſquarroſe, blunt. Corolla yellow with twenty-four rays and two-parted ſtyles: thoſe of the diſk have ſimple longer ſtyles, and are barren [p].
Native of North America. Cultivated in 1766 by Peter Collinſon, Eſq. It flowers from july to october [q].
4. Root perennial. Stem the height of a man, as thick as the thumb, erect, quite ſimple, round except at the bottom where it is indiſtinctly four-cornered, rugged with hairs bent down. Leaves connate-perfoliate, ovate-oblong, with the diſk concave, as in *Dipſacus laciniatus*, ſeſſile and not with the laſt petioles connate-perfoliate as in *S. perfoliatum*, rugged, a ſpan long, ſharpiſh, ſerrate. Panicle terminating, dichotomous: peduncles of the forking ſolitary, one-flowered, length of the internodes. Calyx ſquarroſe, with the ſcales ovate, bluntiſh, even, flat and reflexed at the top, as in *S. Aſteriſcus*. Corolla radiate, yellow: florets of the diſk many, hermaphrodite, abortive, with a ſimple ſtyle ſtanding out:—of the ray twelve, elongated, female, fertile, with a bifid piſtil ſhorter than the corollets [r].
Native of North America. Introduced in 1765, by Meſſrs. Kennedy and Lee. It flowers from july to october [s].]
5. Root perennial. Stem four or five feet high,

[k] Linn. ſpec. [l] Hort. kew. [m] Jacquin.

[q] Hort. kew. [r] Linn. mant. [s] Hort. kew.

thick,

Digitized by Google

thick, ſolid, ſet with prickly hairs, and having many purple ſpots. Lower leaves alternate; upper oppoſite and ſeſſile, rough, about two inches long and an inch broad near the baſe, having a few ſlight indentures on their edges. The upper part of the ſtem divides into five or ſix ſmall branches, terminated by yellow radiated flowers like thoſe of the perennial Sun-flower, but ſmaller, having generally nine florets in the ray.

[Native of North America. Cultivated in 1732, by James Sherard, M.D. from Carolina ſeeds. It flowers from july to ſeptember [t].]

6. Root perennial and woody. Stems annual, riſing five feet high or more in good land, of a purpliſh colour, and branching towards the top. Leaves oblong, rough, having ſome ſharp teeth on the edges; they are from three to four inches long, and almoſt two broad; towards the bottom of the ſtem they ſtand by fours at each joint; higher up they are by threes, and at the top by pairs, ſitting cloſe to the ſtems. Flowers upon pretty long peduncles, ſolitary. Calyx of three rows of imbricate leaves, the outer row ſmalleſt. In the ray thirteen yellow florets, three-toothed at the end.—Native of many parts of North America.

[Cultivated in 1759, by Mr. Miller. It flowers from july to october [u].

7. This is a weakly plant, creeping far among other vegetables, but more luxuriant and upright towards the top.

Native of the Weſt Indies. Frequent in Jamaica, in low marſhy lands [x].]

8. This riſes with a ſhrubby ſtalk to the height of eight or ten feet, ſending out woody branches, with ſpear-ſhaped leaves placed alternately on every part; they are four inches long, and an inch and half broad in the middle, ending in acute points; their ſurface is rough, and their edges ſlightly ſerrate. Flowers terminating, ſome ſingly on ſlender peduncles, others by two or three upon each peduncle, unequal in height. They have ſhort ſcaly calyxes; florets of the ray ſhort; thoſe of the diſk more prominent than in the other ſorts: colour deep yellow.

Diſcovered by Dr. William Houſtoun at La Vera Cruz in New Spain.

PROPAGATION AND CULTURE.

Theſe plants may be increaſed by parting the roots, in the ſame manner as is practiſed for the perennial Sun-flower. The beſt time for this is in autumn, when the ſtalks begin to decay. Treat them afterwards in the ſame way as the perennial Sun-flower.

8. Slip off the young ſhoots in july, plant them in a pot filled with light loam, plunge it in a gentle hot-bed, covering the pot cloſely with a bell or hand-glaſs, and ſhade it from the ſun. When the ſlips are rooted, plant each in a ſeparate pot; place them, during the warm months, in the open air, in a warm ſituation; but in winter keep them in a moderate ſtove.

Eryſimi varietas. *Herm. par.* 155.
Siliques even patulous, leaves lyrate ſmooth, upper lanceolate, ſtem even.

DESCRIPTIONS, *&c.*

1. Root annual, fuſiform, ſmall, rigid. Stem from nine inches or a foot to a foot and half in height, upright, round, ſtriated or grooved, rough with a few ſtiff hairs or briſtles bent ſomewhat downwards, commonly much branched, and the branches ſpreading. Leaves petioled, harſh or rugged, deeply and irregularly indented and ſerrate, ſometimes entire, but moſt frequently jagged at the baſe, and ſometimes lyrate or pinnatifid. Flowers at the ends of the ſtem and branches, each on a pedicel the length of the calyx and ſlightly hiſpid. Calyx-leaves green or yellow, linear, compreſſed-concave, half as long as the corolla, ſtanding open at top. Corolla always yellow. Siliques ſpreading, ſcarce perceptibly angular, (ſubo&tangular, *Sm.*) ſlightly hairy or ſometimes ſmooth, toroſe or ſwelling, ending in a ſhort, compreſſed, enſiform, grooved beak. Seeds dark brown, ſhining, eight or nine [y].

The ſtem is either wholly green or tinged with red. Among corn it is more drawn up, and often ſcarcely branched. The leaves vary much in form and degree of diviſion. The plant differs in height and degree of hairineſs [z].

It is confounded by huſbandmen, under the name of Charlock, with *Raphanus Raphaniſtrum*, which is as common a weed in ſome fields, as this is in others. But the ſtem and leaves of *Sinapis arvenſis* are green without any glaucous caſt; the ſtem hirſute with very rigid hairs; the pods ſmooth and bellying, but not angular; the flowers ſmaller; calyx-leaves ſpreading, yellow, half the length of the petals; corolla ſmaller, yellow and without veins [a].

Native of Europe, in corn fields, flowering in may and june, and perfecting its ſeeds before harveſt; it is therefore very abundant in ſpring corn.

Its claſſical name in Engliſh is Wild Muſtard; but it is known among huſbandmen by the names of Charlock, Garlock, Warlock, Chadlock, Cadlock, and Kedlock, all evidently the ſame name originally, only variouſly pronounced in different counties. We find the laſt in Fitzherbert and our other early Engliſh writers. In ſome parts of Yorkſhire it is ſaid to be called Runſh.

The young plants, and particularly the tender tops before they flower, are boiled and eaten as greens by huſbandmen in Scandinavia, Ireland, and many parts of England.]

The ſeed is commonly ſold under the title of Durham Muſtard-ſeed.

[2. Like the preceding, but the beak only of the pod ſmooth. Native of the Levant.

3. Stature of Cabbage or Lettice, but the calyx of Muſtard. Stem a foot and half high, very ſmooth. Root-leaves oleraceous, obovate, obtuſe, toothed, ſmooth, white-veined, with the petioles channelled: middle ſtem-leaves oblong, ſometimes eared at the baſe of the petiole: upper lanceolate, ſeſſile, embracing. Flower very like that of the common Cabbage. Calyx yellow, ſpreading. Petals yellow, ſcarcely emarginate. Pod like that of Cabbage.

Native of China [b]. Cultivated abundantly both there and in Cochinchina [c].

[y] Fl. ruſt. and Smith. [z] Fl. ruſt. [a] Woodw. Mſs.
[b] Linn. [c] Loureiro.

4. Root

Digitized by Google

4. Root annual. That and the ſtem nearly as in the *arvenſis*. Stem ſtrong, hard, nearly round, upright, branched, ſtriated or finely grooved, ſet with numerous ſtiffiſh hairs pointing downwards, from a foot and half to two feet in height. Leaves petioled, alternate, pale green, rough with ſtrong hairs on both ſides, all deeply indented or lobed, the terminating ſegment very broad and large, and frequently a pair of ſmall wings on the petiole: the lowers ones deeply pinnatifid; the upper ones ſublyrate. Flowers on looſe racemes or bunches at the ends of the branches, on horizontal pedicels, which have four grooves or corners, and ſtrong hairs pointing downwards. Calyx-leaves linear, ſpreading a little at top and ending bluntly, green yellow or ſometimes purpliſh. Petals yellow, with upright narrow claws ſcarcely the length of the calyx; lamina or border obovate and entire. Siliques ſpreading on almoſt horizontal peduncles, an inch long, roundiſh, ribbed, toroſe or ſwelling where the ſeeds are, hiſpid, ſeparated into two cells, by a membranaceous partition, which is produced above the valves into a very long coriaceous, enſiform, flatted, greeniſh, rugged beak. Seeds three or four, globular, very large, white, yellowiſh, brown or dark ruſt colour [d].

Ray diſtinguiſhes this ſpecies from common Muſtard and Charlock, by the leaves being more deeply and frequently cut; the pods hairy and ſtanding out more from the ſtalk; the ſeeds very large, ſo as to ſwell out the pod into knots; and the pod itſelf finiſhing in a broad thin oblong ſword-ſhaped point. Haller remarks, that the flower is larger than in the common Muſtard.

Native of Germany, France, Flanders, Switzerland and Britain, in corn fields, on banks, and by road ſides; flowering in june, and ripening its ſeeds in auguſt. Mr. Curtis obſerves, that Muſtard is as common in the fields about High Wycomb, in Bucks, as Charlock (Sinapis arvenſis) is in other places.

White Muſtard is generally cultivated in gardens as a ſalad herb, with Creſſes, Radiſh, &c. for winter and ſpring uſe. The ſeeds have nearly the ſame properties with thoſe of common Muſtard [e] (Sinapis nigra.)

5. Root annual, ſmall. Stem upright, round, ſtreaked, the upper part ſmooth, three or four feet in height, with many diſtant ſpreading branches. Leaves petioled, variouſly lobed and toothed; thoſe next the root lyrate, rugged; on the ſtem ſmooth, the upper ones frequently ſimple, lanceolate, and ſharply toothed, the very uppermoſt quite entire. Calyx and corolla pale yellow. Siliques ſhort, parallel to the ſtem, with a ſmooth beak: the peduncles are ſlightly hairy. Seeds brown [f].

"Our ordinarie Muſtard," ſays Johnſon, (Gerem. 243.) "hath leaves like Turneps, but not ſo rough, the ſtalks are ſmooth, and grow ſometimes to three, four or five cubits high; they have many branches, and the leaves upon theſe branches, eſpecially the uppermoſt, are long and narrow, and hang downward on ſmall ſtalks; the cods are ſhort, and lie flat and cloſe to the branches, and are ſomewhat ſquare: the ſeed is reddiſh or yellow."

This hanging down of the upper leaves on the branchlets, remarked by Johnſon, diſtinguiſhes this at firſt ſight from its congeners [g].

Ray's diſtinctions are good ones. "It is a loftier plant than either White Muſtard or Charlock; the upper part of the ſtem and the branches are ſmooth; the pods ſhort, preſſed cloſe to the ſtem and almoſt quadrangular. The ſeeds are the ſmalleſt among theſe plants." We may add, that the leaves are of a much darker colour, and their diviſions blunter than in the White Muſtard; the flowers are ſmaller, the pods for the moſt part quite ſmooth, and ſcarcely toruloſe.

Native of Europe, in corn fields, on the banks of ditches, and by way ſides; flowering in june and july. Whenever they throw the earth out of their ditches in the Iſle of Ely, the bank comes up thick with Muſtard; the ſeed falling into the water and ſinking to the bottom, will remain embalmed in the mud for ages without vegetating. The tender leaves are ſometimes boiled and eaten as greens in the ſpring. But it is principally cultivated for the ſeed, which is uſed both medicinally and for culinary purpoſes [h].

The ſeeds reduced to powder make the common Muſtard for the table. When freſh, this powder has little pungency and much bitterneſs; but moiſtened with vinegar and kept for a day, the eſſential oil is evolved, and it becomes conſiderably more acrid. By diſtillation with water they yield an eſſential oil of great acrimony. Subjected to the preſs, they yield a conſiderable quantity of mild inſipid oil, which is as free from acrimony as that of Almonds [i].

The ſeeds unbruiſed taken inwardly, in the quantity of a table ſpoonful or more, gently looſen the bowels, and are of ſervice in aſthma, chronic rheumatiſm and palſy. The powdered ſeeds curdle milk, and give a ſtrong impregnation to boiling water. This infuſion, taken in conſiderable quantity, vomits; in ſmaller doſes it is an uſeful aperient and diuretic. Cataplaſms formed with crum of bread, vinegar and powdered muſtard ſeed are very commonly applied to the ſoles of the feet, as ſtimulants in fevers that require ſuch treatment; they are uſed with advantage, topically applied, in fixed rheumatic and ſciatic pains. Upon the whole, whenever we want a ſtrong ſtimulus, that acts upon the nervous ſyſtem, without exciting much heat, we know none preferable to Muſtard ſeed. Its acrimony is not to be aſcribed to volatile alkali, but conſiſts in an eſſential oil [k].

Bergius informs us, that he found Muſtard of great efficacy in curing vernal intermittents; for this purpoſe he directed a ſpoonful of the whole ſeeds to be taken three or four times a day, during the apyrexia; and when the diſeaſe was obſtinate, he added flour of Muſtard to the bark. Muſtard-ſeed may be moſt conveniently given entire or unbruiſed, and to the quantity of a ſpoonful or half an ounce to a doſe [l].

6. Root biennial. Leaves runcinate, ſmooth, with a whitiſh rib; the triangular ſegments of the root-leaves toothletted, of the ſtem-leaves lanceolate. Stem ſmoothiſh. Flowers racemed, ſmall, yellow. Siliques ſtraightiſh, ſtriated, rugged, with indiſtinct hairs pointing upwards [m].

Stems angular, even, round, ſtriated, flexuoſe, ſmooth. Margin of the leaves and rib ſhortly ſubhirſute: the leaves themſelves pinnatifid, with the pinnas triangular, toothed eſpecially below, on a grooved petiole. Flower-ſtalks from the axils of the leaves. Flowers firſt in an umbel, afterwards in a raceme. Pedicels round. Calyx-leaves linear, greeniſh-yellow, about the length of the claws. Petals ovate, quite entire. Siliques ſtriated, toroſe, round. Seeds ten or twelve, oblong, grooved in the inner part [n].

Native of the Pyrenees, mont Cenis, the Alps of the Vaudois and di Viu.

β. This, according to Allioni, differs not only in its place of growth, but in ſome other marks. The biennial roots bear the root-leaves on long petioles, ſinuate-angular eſpecially towards the petiole. The ſtem-leaves are more ſparingly toothed, and longer with the end triangular; the upper ones ſcarcely angular and rather haſtate. All juicy and thickiſh, very ſmooth, ſubglaucous, concave above. Stem a yard high, firm, erect, branched, round, very ſmooth; with a raceme of flowers on each branch. Calyx ſpreading. Petals ovate, clawed, ſulphur-coloured. The peduncles thicken after flowering. Siliques irregularly preſſed cloſe to the branches and commonly twiſted, round, toruloſe, narrower towards the end, thickened (but not horned or beaked) with a two-necked permanent ſtigma. In the other the ſtigma is not cloven.

Native of the coaſt of Uneglia, the deſcent of the Col di Tenda and the following mountains towards Nice, &c.

7. Stem perennial, ſhrubby. The whole plant

Digitized by Google

villoſe. Leaves blunt. Petals yellow, entire.—Native of Sicily [o].

8. Root annual. Stem hiſpid-muricated. Leaves pinnatifid, blunt, toothed, the end lobe oblong and very large, very rugged on both ſides with ſhort rigid hairs. Petioles hiſpid. Flowers yellow. Beak of the ſilique long, blunt and flat.—Native of Morocco [p].

9. Root annual. Stem hiſpid below. Leaves toothed, rugged about the edge and along the rib. Flowers white, ſmall [q].

Stem three feet high, thick, ſtriated, branched. Root-leaves large, oblong-oval, lyrate-runcinate, wrinkled, with few hairs, often none: petioles roundiſh, channelled, ſhort, fleſhy. Stem-leaves cordate-conical, embracing, ſubſerrate, alternate, ſmooth, with rounded ears. Flowers terminating, yellow, in long ſimple ſpikes. Siliques toroſe; containing brown, globular ſeeds.

Native of China and Cochinchina, and very extenſively cultivated in both countries.

There are two varieties of it in Cochinchina, with entire leaves, not lyrate. Theſe being more tender and having more flavour, are preferred for eating. The ſeeds are uſed internally as a ſtimulant, and externally as ſinapiſms [r].

Introduced in 1782 by Monſ. Thouin; and flowering here in july [s].

Loureiro has another ſpecies, (S. pekinenſis) which is cultivated about Pekin, and eſteemed the beſt of all the ſorts. It grows higher in Cochinchina, but is inferior in quality. Loureiro ſowed the ſeeds in Portugal, on his return home, but found that it degenerated every year. He deſcribes it as annual, two feet high, with an upright, thick, round, ſmooth ſtem: the root-leaves turbinate-ovate, entire, ſerrate-runcinate, curled, ſmooth, yellowiſh, very tender; on flattiſh, very wide, white, grooved, half-embracing petioles; ſtem-leaves conical, ſeſſile, quite entire. Spikes ſolitary, very long, ſpreading. Calyx-leaves oblong, blunt, upright, yellow. Corolla yellow, ſpreading. Siliques linear, compreſſed, ſmooth. Seeds globular, rufous.

Loureiro regards *Sinapis juncea* and *cernua* as varieties of the *chinenſis*; and conſidering how the Cabbage varies in Europe by culture, he doubts whether all theſe plants may not be varieties, rather than true ſpecies.]

10. Stems three or four feet high. Root-leaves broad, ſmooth, jagged; but the upper ones are entire. Flowers yellow. Pods ſmooth and turgid.

Native of China, whence the ſeeds are frequently brought to England. This plant is uſed as a boiled ſalad by the Chineſe, but in England it is not regarded. It flowers in june and the ſeeds ripen in auguſt.—Calyx hairy, pale green: flowers white.

[Cultivated in 1731, by Mr. Miller [t].

11. Root fibrous, white, and annual: the whole plant is either perfectly ſmooth, or at moſt ſcattered over with a few diſtant whitiſh hairs: ſtem ſolitary, round, branchy, and about a foot and half high: all the leaves laciniated in a pinnatifid manner, rather obſcure, inſipid, with the ſegments unequally tooth-pinnated: upper leaves ſeſſile, the reſt footſtalked: no radical leaves, except the ſeed-leaves: flowers thinly placed on upright racemes, almoſt inodorous: calyx yellowiſh, with a tinge of green: petals yellow: ſiliques ovate-oblong, wrinkled, glaucous, not at all hairy, and marked by a few longitudinal prominent lines [u].]

12. This ſeldom riſes more than eight or nine inches high. Leaves ſmooth and much jagged. The ſtalk branches towards the top, and is terminated by a looſe ſpike of white flowers; theſe are ſucceeded by ſmooth, taper, blunt pods, filled with ſmall brown ſeeds. It flowers in june, and the ſeeds ripen in auguſt.

[Root annual. Stem purpliſh, ſomewhat angular, rugged. Leaves lyrate-runcinate, ſharpiſh, ferrulate. Racemes corymbed. Calyx half-ſpreading, pubeſcent. Petals white, obtuſe, ſcarcely emarginate. Filaments purpliſh [x].

Native of Italy and Spain, in vineyards and by way ſides.

13. The whole plant is ſmooth. Root-leaf lyrate: lobes nearly oppoſite, oblong, entire, half an inch long, the length of the internodes: terminating lobe ovate, obtuſe, gaſhed, toothed with wide teeth, little curled, nerved, almoſt the ſize of a Cabbage leaf. Stem-leaves ſubſeſſile, oblong, entire below, toothed above, nerved, a finger's length, with the upper ones gradually ſmaller. Stem ſtriated, ſmooth, branched at top. Flowering-branches drooping. Flowers terminating, racemed, white. Peduncles capillary, ſpreading. Siliques linear, attenuated at the top, even, ſmooth.

Native of Japan [y], and China. Annual.

14. Native of Spain. Cultivated in 1759 by Mr. Miller, who has however given no deſcription of it.

15. The whole plant is ſmooth and herbaceous. Stem erect, ſtriated, even, branched. Branches ſpreading, like the ſtem, ſubdivided. Leaves petioled, rounded at the corners, acute, a finger's length: the upper ones leſs deeply pinnatifid, often toothed at the end. Raceme of flowers very long. Peduncles capillary, from ſpreading upright. Corollas yellowiſh. Siliques erect, ſomewhat angular, ſmooth and even, attenuated at the top.—Native of Japan about Jedo, flowering in may [z].

16. Root branched, hard, acrid, having the taſte and ſmell of *Braſſica Napus* or Navew. Root and ſtem-leaves on long petioles, lyrate, very hairy, hoary, with the lobes ovate, decurrent, alternate, toothed: axillary leaves lanceolate-linear, quite entire, ſeldom toothed. Stem panicle-branched, hiſpid, with hairs pointing backwards. Branches ſtiffiſh. Racemes terminating and axillary. Flowers ſmall, yellow. Siliques preſſed cloſe to the raceme, as in *Eryſimum officinale*, at firſt rough-haired, then ſmooth, compoſed of one lower long many-ſeeded joint, and one upper ſhorter commonly one-ſeeded. Style very ſhort. In gardens the ſtem is more upright, leſs branched, ſmoother, leſs hoary, with branches leſs wandlike [a].

Native of France, Spain, Portugal and Switzerland. Introduced in 1778, by Monſ. Thouin. It is biennial and flowers in july.

17. Native of the iſland of Madeira. Introduced in 1777, by Mr. Francis Maſſon. It flowers from december to june [b].

18. Root perennial, very long, twiſted, having filiform branches. Stem hiſpid at the baſe, ſmooth above, even, erect, with long, erect branches. Root-leaves and lower ſtem-leaves petioled, hiſpid, deeply lyrate; with the pinnules alternate, remote, obtuſe, often narrowed at the baſe, unequally toothed, with ſmaller ones interpoſed; the end-lobe larger, rounded or oblong. Middle and upper ſtem-leaves few, remote, pinnate, ſmooth, with the pinnules lanceolate or linear-lanceolate, acute, entire or toothed. Flowers of the ſame ſize as in *S. juncea*. Calyx coloured, looſe, with linear-elliptic leaflets. Petals pale yellow, with the border obovate and quite entire. Siliques looſely racemed, pedicelled, toruloſe, ſmooth, ſpreading, with an awl-ſhaped point. Pedicels filiform, a little ſhorter than the ſilique.—Near Algiers, on barren hills [c].

Desfontaines has other ſpecies: as 1. *Sinapis circinata*. Pubeſcent all over, with an upright, ſtriated ſtem, ſparingly branched. Leaves petioled, ſoft: the upper ones ſimple, toothed, ovate, obtuſe; the lower pinnate-lyrate, pinnules three or five, unequally crenate; the end lobe very large, circinate, crenate, the other lobes ſmaller, oblong, obtuſe, unequal. Flowers in racemes, pedicelled. Calyx pubeſcent, coloured, patulous, deciduous. Corolla yellow, the ſame ſize as in *S. arvenſis*: border obovate, quite entire. Germ pubeſcent. It is an annual plant, found among corn in Barbary.

2. *Sinapis recurvata*. *Allion. pedem. n.* 963. *t.* 82. *f.* 1. Root perennial (biennial, *Allion.*) Leaves petioled,

Sinapis Harra. *Forſk. deſcr.* 118.
Cauleſcent, leaves petioled oblong toothed hiſpid, ſtem alſo hiſpid.

DESCRIPTIONS, &c.

1. Roots perennial, conſiſting of long white fibres, the lowermoſt fixed in the ſoil, the reſt ſuſpended in the water. Stems ſpreading, declining or floating, angular, branched, leafy. Leaves alternate, pinnate, ſomewhat lyrate, the terminating and upper leaflets being the largeſt: all the leaflets roundiſh, more or leſs heart-ſhaped, ſmooth, ſhining, waved or toothed, frequently tinged with a purpliſh brown hue. Flowers white, in a corymb, ſoon lengthened out into a ſpike. Pods ſhortiſh, on horizontal pedicels, but the pods themſelves recurved upwards. Stigmas nearly ſeſſile[1].

According to Curtis, the root is annual. Withering marks it as biennial. Stems numerous, from a foot to two feet or more in height. Leaves half-embracing, compoſed of three or four pairs of leaflets, which are oppoſite, ovate, obtuſe, with a ſlight indentation at the end, bluntly toothed, ſeſſile, the end leaflet rounder and larger, often running out to a point. The leaves, when the plant grows in the ſhade, are green; when expoſed to the ſun, purpliſh brown: when growing in a rapid current, they are ſometimes conſiderably lengthened out; as is the caſe with other plants in the ſame circumſtances. In this ſtate, there is a poſſibility that the leaves may be miſtaken for thoſe of the creeping Water-Parſnep (Sium nodiflorum), which commonly grows with it; but the leaves of the Water-Parſnep are not only long and pointed, but ſerrate, of a much paler colour, and without any of that creſs-like taſte, which is to be found in Water-Creſſes[2].

[1] Engl. bot. [2] Curtis.

Native

Digitized by Google

S I S

Native of Europe, Asia, Africa and America, in ſprings, pools and rivulets; flowering in june and july.

Water-Creſs is reputed an excellent antiſcorbutic, with leſs acrimony than Scurvy-graſs. It is ſuppoſed to purify the blood, and to open viſceral obſtructions. In the ſpring it is very frequently eaten as a ſalad. The juice is directed, with that of Scurvy-graſs and Seville Oranges, and thus forms a popular remedy, under the name of Spring juices [t].

2. Root perennial, whitiſh, ſlender, remarkably creeping, thickly beſet with germs, which give it a knobbed appearance. Stems numerous, a foot high, upright or nearly ſo, leafy, flexuoſe, weak, ſometimes purpliſh, ſmooth, ſomewhat angular and finely grooved, branched: the branches very ſlightly hairy, forming a ſort of panicle. Leaves alternate, pinnate, ſmooth; leaflets in the lower decurrent, elliptic, oblong, toothed, in the upper, narrower, ſubpetioled, gaſh-ſerrate. Petioles channelled above, often purpliſh. Common peduncle flexuoſe; pedicels alternate, ſpreading almoſt horizontally or bent a little upwards, generally longer than the pod; all together forming finally very long racemes. Calyx-leaves ovate, concave, upright, equal, yellowiſh. Corolla ſmall, yellow or gold-coloured; petals obtuſe, a little longer than the calyx. Nectary of four deep-green glands, united in a circle. Filaments yellow: anthers incumbent. Germ the length of the ſtamens: ſtyle very ſhort: ſtigma villoſe. Silique ſcarcely half an inch long, cylindrical, curved upwards, generally abortive, as is frequently the caſe in plants that increaſe very much by the root. Both Ray and Tournefort mention the ſeeds; it is probable therefore that they found it in dry ſituations favourable to their ripening [u]. The pod then aſſumes an oblong-ovate form, as Linneus deſcribes it [x].

Mr. Woodward ſays, that he never found the pods producing perfect ſeeds; and remarks, that the pedicels are indeed at firſt parting from the branch curved downwards, but the pod itſelf riſes upwards, which cannot anſwer to Linneus's deſcription of *ſiliquis declinatis*.

Native of Sweden, Britain, Germany, France, Switzerland, Carniolia, Piedmont, Siberia. From Tournefort, who has deſcribed the plant with much accuracy, it appears to be plentiful, not only along the banks of the Seine, but in the courts of houſes, and moſt moiſt ſituations. With us it is not of ſuch general growth, but where it does occur, it is found in great abundance. The watery part of Tothill-fields, Weſtminſter is overrun with it [y], and it is found on the banks of the Thames in ſeveral places. On Cambridge common; between Cheſterton-ſluice and Barnwell-pool; and in the Iſle of Ely. On Bungay common in Suffolk. In Bedfordſhire frequent. In Oxfordſhire, on the banks of the canal beyond High-bridge, Port meadow, Binſey common, and Otmore. On the banks of the Severn near Worceſter. On the banks of the Aire below Leeds [z].

3. The annual Water-Rocket, which was probably unknown to Linneus, and was confounded by Hudſon, with the great Water-Rocket or Water-Radiſh, differs from it in the following circumſtances: 1. It is an annual plant, whereas the *amphibium* is not only a perennial, but has a creeping root. 2. It is a much ſmaller plant, ſeldom acquiring half the height of the *amphibium*. 3. It is ſeldom in water, except accidentally. 4. Its foliage is very different, the radical leaves much reſembling thoſe of *Eryſimum officinale*. 5. The ſeed-veſſels are always turgid, and full of ſeeds, while thoſe of the *amphibium* are uſually abortive [a].

To theſe marks it may be added, that the root is ſimple, fuſiform and ſmall; the ſtem generally upright, branched, a foot high and ſmooth; the leaves lyrate-pinnatifid, ſmooth, unequally and obtuſely tooth-ſerrate; the flowers ſmall, the petals being ſhorter than the calyx, and ſometimes emarginate; the fruiting racemes very long; the ſiliques ſpreading horizontally, a little curved in, ſhort, obtuſe, even, many-ſeeded (twenty), terminated by a very ſhort ſtyle [b].

Mr. Woodward remarks, that the pinnas of the upper leaves are lanceolate and toothed, the terminating one very large, confluent with the next pair, deeply indented.

When this plant happens to be overflowed, which is frequently the caſe, it is then more procumbent, and will ſometimes take root at the joints; in which ſtate it appears to be the *Siſymbrium paluſtre repens, parvo flore* of Vaillant.

It has a taſte ſimilar to moſt plants of the Creſs kind, but is not very pungent.

Common about London, with *Rumex maritimus*, on the edges of wet ditches, and on ground apt to be occaſionally overflowed; as on Tothill-fields, &c. [c] Hauxton in Cambridgeſhire, and near Ely-bridge [d]. Elſtow and Goldington in Bedfordſhire [e]. Oxfordſhire, near the Diamond Houſe [f]. On Bungay common in Suffolk, by Mr. Woodward.—It flowers from june to ſeptember.

4. Root perennial fibrous. Stems elongated, rooting, ſomewhat flexuoſe, leafy, grooved, little branched. Leaves alternate, oblong, ſerrate or pinnatifid; the upper ones commonly quite entire; the radical ones petioled, and when they grow out of the water ſometimes pubeſcent. Flowers yellow, with the petals longer than the calyx. Germ pedicelled, globular. Siliques very ſhort, terminated with the elongated ſtyle [g]. According to the obſervation of Mr. Woodward, they are at firſt ſpreading, but afterwards hang down, and the fruitſtalks are much longer than the pods themſelves. This differs materially from the *terreſtre* in theſe particulars: the pods being not above half as long, and hanging perfectly down, and yet the fruitſtalks being much longer than the other.

In rivers and brooks, and ſometimes on the banks that are ſeldom overflowed, in moſt parts of Europe: flowering from june to auguſt.

5. Root perennial. Petioles embracing. Style capillary. Silique oval [h].

Stem-leaves bipinnate, with the pinnules linear, acute and quite entire. Flowers yellow [i].

Dillenius, Haller and Allioni have ſeparated this from Siſymbrium, each under a different name, on account of the ſhortneſs of the pod.

Native of the Pyrenees, Aragon, Dauphiné and Switzerland.—Introduced in 1775, by Monſ. Thouin. It flowers in may and june [k].]

6. Leaves finely divided, ſomewhat like thoſe of Tanſy, but of a hoary green colour. The ſtalks riſe a foot and half high, fully clothed with leaves of the ſame form, but gradually diminiſhing in ſize upwards. Flowers in terminating cluſters, ſmall and pale yellow. Pods ſlender, taper, two inches long. Seeds ſmall and round.

[Height from two to three feet. Stems ſtraight, and ſimple except a few branches at the top. Leaves, though green, covered with ſtellate hairs, and ſo like thoſe of Tanſy, that one might be deceived were it not that they want the peculiar ſmell of that herb. Corolla yellow, in a coloured calyx ſhorter than the petals. Siliques ſtraight and thin [l].

Guettard and Villars would make a diſtinct genus of this and Sophia.

Native of Italy, Dauphiné and Switzerland.—Cultivated by Mr. Miller in 1731 [m].

7. Root annual. Stems aſcending or erect, ſlender, branched below, pubeſcent. Leaves ſmooth or ſlightly pubeſcent; lower toothed, upper quite entire. Calyx ſmall, coloured. Corolla yellow, twice as long as the calyx; border of the petals obovate, quite entire. Siliques ſmooth, ſlender, compreſſed a little, diſpoſed in a naked, looſe, long raceme, on filiform pedicels almoſt twice their length. Style very ſhort. Seeds four, five or ſix, ſmall, rufeſcent. Allied to *S. ſorenſopifolium*, but differs in having linear leaves, twice or

[t] Woodville, Withering. [u] Curtis and Smith. [x] Smith. [y] Curtis. [z] Smith and Withering. [a] Curtis. [b] Smith. [c] Curtis. [d] Relhan. [e] Abbot. [f] Sibthorp. [g] Smith. [h] Linn. ſpec. [i] Aſſo. [k] Host. kew. [l] Villars. [m] Hort. kew.

thrice

S I S

thrice narrower than in that. Found in ſands near Caſſa in Barbary.

8. Lower leaves almoſt like thoſe of *Plantago Coronopus*, with the teeth remote, linear, entire, uniform, pectinated, ſhorter or longer. Stems often many, ſimple or little branched, diffuſed or decumbent at the baſe, villoſe, very ſlightly ſtriated. Calyx pubeſcent, looſiſh, coloured, deciduous, with elliptic leaflets. Corolla twice or thrice the length of the calyx, yellow, border of the petals obovate, quite entire. Style none. Siliques ſlender, ſmooth, in looſe racemes, compreſſed a little, many-ſeeded, on filiform, pubeſcent pedicels, ſcarcely longer than the ſilique. It flowers in winter.—Native of the deſert near Caſſa, in ſands [a].

9. Root perennial, fuſiform, whitiſh, ſomewhat woody. Stem very much branched, a foot and half high, leafy, round, glaucous, ſmooth with ſometimes a few ſcattered hairs. Leaves rather fleſhy, glaucous, quite entire or ſometimes ſlightly notched; the uppermoſt generally but not always ſimple. Flowers large, lemon or ſtraw-coloured, handſome but ſmelling unpleaſantly. Calyx ſpreading, commonly rough-haired at the end. Siliques erect, oblong, ſmooth, round, with a raiſed line on each ſide; terminated by a ſhort ſtyle. Seeds elliptic, compreſſed. Every part of the herb is pungent to the taſte [b].

Mr. Curtis remarks, that the calyx, before it opens, appears to have two little ſhort horns, from each of which iſſue one or more fine hairs; that when the flower is expanded two of the calyx-leaves ſtand almoſt upright, while the other two bend back; and that two of the four glands are uncommonly long.

Mr. Hudſon at firſt took this plant for Linneus's *Braſſica Erucaſtrum:* in his ſecond edition he called it *Braſſica muralis*, quoting *Siſymb. murale* as a ſynonym, which is very different. Linneus adopted his *S. tenuifolium* from Dalibard, without ſeeing a ſpecimen, nor is it, as ſuch, in his herbarium. The ſpreading calyx makes it a *Siſymbrium*, not a *Braſſica*, ſo that there is no occaſion to recur to the uncertain mark of the nectariferous glands. The name *tenuifolium*, taken from John Bauhin, is certainly exceptionable, ſome of the genus having much more finely cut leaves [c]. *Muralis* would have been better, had it not been preoccupied.

Native of Germany, France, Piedmont, Switzerland and England: flowering from july to october. On many old walls and caſtles throughout England, about the Tower of London, London Bridge, Bethlehem Hoſpital, Hyde Park, &c. Windſor, Cheſter, Briſtol, Yarmouth, Lichfield, Taunton, Exeter, Berwick, Sunderland, Tinmouth, &c.

Linneus latterly confounded this with his *S. catholicum*, which has ſharply ſerrate leaves, and is a ſmaller more delicate plant [d].

10. The radical leaves petioled haſtate or ſubruncinate [e]. Perennial. Native of Siberia. Introduced in 1780, by Peter Simon Pallas, M. D. It flowers in may and june [f].

11. Root annual. Stems even, erect, having a few ſhort hairs at the baſe, ſmooth above, branched, ſlightly ſtreaked. Branches ſlender, erect, ſpreading. Leaves ſmooth; radical and lower ſtem-leaves obovate or wedge-form, ſomewhat toothed, running down the ſhort petiole; middle and upper ſtem-leaves few, remote, embracing, lanceolate or cordate-lanceolate, toothed or quite entire. Calyx ſmall, with elliptic, coloured leaflets. Petals yellow, twice or thrice the length of the calyx, with an ovate border quite entire. Style ſhort, acute, permanent. Siliques forming a raceme, ſpreading, erect, on capillary pedicels, ſmooth, ſlender, compreſſed a little, drawn to a point at each end, mucronate at the tip, ſhorter by half than the pedicel, or nearly ſo. Seeds from three to five, very ſmall, ruſeſcent. It flowers early in the ſpring.

Native of the hills about Algiers [g].

12. This is an annual plant, native of the South of Europe; flowering in june and july. Introduced in 1778 by Monſ. Thouin [h].

13. This differs from the preceding in having the teeth of the leaves ſharper, and the ſiliques not ſolitary in the axils of the leaves. Annual [i]. According to Allioni it is biennial.

Haller remarks, that in leaves and flower it agrees entirely with the common Hedge-Muſtard, *Eryſimum officinale*, which Allioni conſiders to be of this genus; but the leaves are ſmooth, with fewer and wider pinnas; upper leaves entire, triangular as in *Atriplex*, or ſemipinnate, with the nerve leſs denudated than in *Eryſimum*, and not pinnate. Flowers ſmall, yellow. The whole ſilique different, erect, curved, two or three together, in bundles, ſeſſile: partition hollowed out deeply. Seed very ſmall.]

Miller deſcribes it as an annual plant, with the ſtalks ſpreading and declining, a foot long, and dividing into many branches. Leaves ſmooth, ſhaped like the point of a halbert, deeply ſinuated and indented, with the indentures turning backward. Flowers in axillary cluſters, ſmall and yellow. Pods ſlender, crooked in cluſters. It flowers in june and july.

Native of the South of France, and of Italy, [and Switzerland.—Johnſon ſaw it in the garden of Maſter Parkinſon, who muſt therefore have cultivated it before 1633 [k].

14. This is a very ſmall annual, not more than an inch and half or two inches in height. Leaves ſubſeſſile, an inch long, ſmoothiſh, very narrow, ſharpiſh, the upper ones ſometimes bifid. Flowers ſmall. Petals white, linear, obtuſe, a little longer than the calyx. Siliques linear, blunt, ſomewhat rugged.—Native of Siberia, by the river Kuma [l].

15. Annual. Native of Italy, in moiſt places on mountains. It is doubtful whether Linneus's plant be the ſame with Gouan's or Allioni's, &c. See Villars.

16. Stems branched, rough with ſhort ſpreading hairs. Branches ſpreading, hirſute, rigid. Leaves pubeſcent, decurrent along the ſhort petiole. Flowers ſmall. Calyx hirſute, coloured; with linear leaflets. Petals white, a little longer than the calyx; border obovate, quite entire. Style none or very ſhort. Stigma thickiſh. Siliques in racemes, ſlender, awl-ſhaped, round, toruloſe, erect, villoſe. Seeds ſmall, many. There are often ſome racemes of flowers from the root. It flowers early in ſpring.

Native of the kingdom of Tunis near Shiba, in fallows [m].

17. Root annual. Stems ſomewhat rugged, having a few ſtiff hairs ſcattered over them, branched and leafy above the baſe. Leaves petioled, oleraceous, having a few ſcattered hairs underneath. Scapes long, at firſt decumbent, and then aſcending. Calyxes half-ſpreading arched at the top, having a few hairs. Corollas yellow, very blunt, large, the diameter of the leaves. Siliques thickiſh, compreſſed a little, with the valves indiſtinctly keeled [n]. It differs in very few circumſtances from the next ſpecies. The leaves are indiſtinctly or only here and there and very remotely ſerrate [o].

The conſtant characters of this are, longiſh hairs at the bottom of the ſcape, which ſometimes becomes a ſtem; a villoſe calyx, a little gibbous at the upper part exteriorly; and petals of a deep yellow colour, very blunt or ſlightly emarginate: there are alſo two glands at the baſe of two of the petals, ſharp like the point of a pin, ſometimes a quarter of a line in length, but often ſhorter. Leaves often ſmooth, but ſometimes a little villoſe. Petals as long again as the calyx. Siliques an inch in length, a little gibbous, on a ſhort peduncle [p].

Native of France and Italy. On the 6th of october, 1801, L. W. Dillwyn, Eſq. ſent information to the Linnean Society of London, that he had diſcovered this plant growing wild abundantly on the pier at Ramſgate and other places thereabouts; and that

petioled, ſmooth, deeply pinnate-lyrate; with the lobes diſtinct, unequal, acute or obtuſe, running down the petiole; the end one larger, ovate, unequally toothed. Flowering branches ſmooth, ſimple, leafy at the baſe, naked above, aſcending. Flowers pedicelled, racemed. Calyx ſmooth. Petals pale yellow. Siliques ſmooth, toruloſe, awl-ſhaped at top, pedicelled, looſely racemed, when ripe nodding.

Found by Bellardi in Piedmont, and by Desfontaines in the clefts of rocks on mount Hamamelif near Tunis.

3. *Sinapis bipinnata.* This has the appearance of a *Siſymbrium*, and perhaps may belong to that genus. Root annual. Stem erect, ſlender, ſimple or ſparingly branched, tubercled, rugged, hairy, with ſhort hairs turned back. Leaves petioled, ſmooth, bipinnate; pinnules linear, unequal, entire or toothletted. Flowers at firſt in a corymb, afterwards in a raceme. Calyx ſmall, ſmooth; leaflets linear-elliptic, obtuſe. Petals pale yellow, with the claw longer than the calyx, and the border obovate and entire.—Native of the mountains of Caſſa.

4. *Sinapis geniculata.* Allied to *S. nigra*, but differing in having the ſiliques more ſlender, ſtriated, pubeſcent, with the point bluntiſh, longer, jointed and bent in. It is an annual plant found among corn in Barbary [d].

10. This is a biennial plant, native of Spain and Portugal. Introduced in 1770, by Monſ. Richard. It flowers in june [e].

PROPAGATION AND CULTURE.

1. This and the other ſpecies, when they are weeds among corn, being annuals, may be deſtroyed, or at leaſt checked, by ſpring-feeding with ſheep, or by weeding with the hook, to prevent its flowering. The ſeed will lie in the ground, till turned up within the ſphere of vegetation; by which means it may be deſtroyed on fallows.]

4. White Muſtard is chiefly cultivated in gardens for a ſalad herb in the winter and ſpring. For this purpoſe ſow the ſeeds very thick in drills, upon a warm border, or in very cold weather upon a moderate hot-bed. They will be fit for uſe in ten days or a fortnight, for if they are large and have rough leaves, they are too ſtrong to put into ſalads.

To ſave the ſeeds, a ſpot of ground muſt be ſown in the ſpring, and when the plants have four leaves, hoe the ground in the ſame manner as for Turneps, in dry weather. In a month hoe the ground over again, leaving the plants eight or nine inches aſunder. If this be well performed, and in dry weather, the ground will remain clean till the ſeeds are ripe. As ſoon as the pods change brown, cut the plants off, and ſpread them upon cloths two or three days to dry, and threſh them out for uſe.

5. Common Muſtard is cultivated only for the ſeeds, which ſhould be ſown in the ſame way as thoſe of the preceding, and treated in the ſame manner, only allowing the plants twice as much room, or hoeing them out to the diſtance of eighteen inches. Sometimes this ſort requires to be hoed three times.

The other ſorts are cultivated only for variety, and may be treated in the ſame way.

Claſſ. 4. 1. Tetrandria Monogynia.

Nat. order of *Borragineæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-parted, wide, permanent.

COR. one-petalled, funnel-form: *tube* filiform, very narrow, ſeveral times as long as the calyx: *border* four-parted, ſpreading, leſs than the calyx.

STAM. *Filaments* four, longer than the border of the corolla. *Anthers* oblong, triangular.

PIST. *Germ* four-cleft, very ſhort, ſuperior. *Style* filiform, length of the ſtamens, recurved at the tip. *Stigma* ſimple.

PER. *Berries* four, with the ſpreading calyx, roundiſh.

SEEDS ſolitary, roundiſh.

ESSENTIAL CHARACTER.

Cor. one-petalled, funnel-form, very long, inferior. *Berries* four, one-ſeeded.

SPECIES.

1. Siphonanthus indica.

Lin. ſpec. 159. *ſyſt.* 152. *Reich. 1.* 310. *Willd* 1. 606. *Amm. act. petrop.* 1736. *p.* 214. *t.* 15. *Lamarck encycl. t.* 79. *f.* 1.

Border of the corolla ſpreading, ſtigma undivided.

2. Siphonanthus anguſtifolia.

Lin. ſpec. ed. Willd. 1. 606. *Lamarck encycl. t.* 79. *f.* 2.

Border of the corolla two-lipped, ſtigma bifid.

DESCRIPTIONS, &c.

1. Stem herbaceous, quite ſimple. Leaves oppoſite and alternate, linear-lanceolate. Flowers in axillary corymbs, three or four together. Border of the corolla flat, with the ſegments ſpreading and acute. Anthers triangular, ſagittate. Stigma undivided, thickiſh. Native of South America.

2. This has leaves like thoſe of the preceding, but much narrower, and by threes. Flowers axillary in bifid corymbs ſix-flowered or three-flowered. Tube of the corolla curved in; ſegments of the corolla blunt, three of them bent back, the uppermoſt erect, as in a labiate flower. Anthers roundiſh. Stigma bifid [f].

7. Siſon crinitum.
Lin. ſpec. ed. Willd. 1. 1438. *Pallas act. petrop.* 1779. 2. *p.* 250. *t.* 7.
Root-leaves triplicate-pinnate, ſtem-leaves bipinnate, leaflets briſtle-ſhaped, univerſal involucre many-leaved bipinnate.

DESCRIPTIONS, &c.

1. Root annual or biennial, ſpindle-ſhaped, with lateral branches. Stem erect, two or three feet high (except in dry places), much branched and ſpreading, rather flexuoſe, round, furrowed, ſmooth, leafy. Leaves pinnate with a terminating lobed leaflet, unequally ſerrate: the lower ones have ſeven or nine leaflets, ovate, gaſhed, ſerrate, ſometimes compound; the upper ones have the leaflets narrower, deeper cut, and often pinnatifid. Umbels numerous, terminating, ſolitary, erect when in flower, compoſed of four, ſeldom more, unequal rays; with a ſmall four-leaved general involucre. Partial umbels likewiſe have but few rays, and thoſe unequal, with a ſmall four-leaved partial involucre. Calyx ſcarcely perceptible. Petals white, inflexed, broader than thoſe of *S. ſegetum.* Fruit ovate, ſhort, compreſſed, ribbed. Seeds aromatic and pungent when ripe and dry; but in an early ſtate they, like the whole herb, have a peculiar nauſeous ſmell[g].

Native of England, Germany, South of France, Carniola and Piedmont. With us not unfrequent in moiſtiſh ſpots under hedges, where the ſoil is marly or chalky, flowering in the latter part of ſummer.

2. Root ſmall but ſtrong, annual in general but often biennial. Stems very much branched, round, ſtriated, ſlender and ruſh-like, leafy. Leaves unequally pinnate; leaflets numerous, ovate-roundiſh, ſerrate, ſcarcely gaſhed, the end one trifid; radical leaves largeſt, conſiſting of from ſeven to fifteen leaflets. General umbels of few (two or three) very unequal rays. Partial umbels nodding, few-flowered, with the pedicels of various lengths. Involucre two-leaved, lanceolate. Involucrets moſtly five-leaved, ovate, acute, concave. Flowers very ſmall, regular, white or fleſh-coloured. Calyx five-toothed. Petals incurved. Anthers purple. Fruit oblong-ovate, doubly ribbed, pungent and aromatic, as is the whole plant in ſome degree[h].

Native of Switzerland and England, in corn fields in a chalk and clay ſoil, but not very frequently. Obſerved by Goodyer about Mapledurham, Hants, long before 1620, in which year he deſcribed it. The whole account of this herb by this accurate obſerver, with the origin of its name *Honewort*, from its curing a ſwelling in the cheek called a *Hone*, with the hiſtory

[g] Engl. bot. [h] Smith brit. & engl. bot.

of

Digitized by Google

of Miſtris Urſula Leigh, and Miſtris Charitie Leigh, is a model of accurate inquiry and preciſe information [l]. It occurs in Madingley road near Cambridge, and about Haddenham, in the iſle of Ely. About Goldington and Clapham in Bedfordſhire. Found near Kelmarſh in Northamptonſhire by William Hanbury, Eſq. At South Leigh, in Oxfordſhire, by Dr. Sibthorp. At Binham in Norfolk by Mr. Crowe. At Walthamſtow in Eſſex by Meſſrs. Forſters. It flowers in july and auguſt.

3. Root perennial. Radical leaves ternate, ſerrate; the middle leaf trifid, the two ſide ones bifid. Stem-leaves ternate, ſerrate, lanceolate, ſhining. Umbel four-cleft, unequal, without any involucre. Umbellets moſtly ſeven-flowered, with a very ſmall involucret. Petals white, equal. General involucre none [k].

Stem round, upright, ſmooth, little branched, two feet high and more. Leaves petioled, all ternate, paler beneath, ſmooth, the lower ones larger, the upper gradually leſs: leaflets ovate, acute, gaſhed, ſharply ſerrate, almoſt equal, the lateral ones ſeſſile, the middle one ſubpetioled. Radical petioles capillary, ſmooth, many times longer than the leaves; thoſe of the ſtem-leaves a little ſhorter. Flowers axillary, panicled and umbelled. Peduncles and pedicels capillary, looſe, ſmooth. Corollas white. Seeds oblong, ſcored, ſmooth [l].

Native of North America and Japan. Introduced before 1699, by William Sherard, Eſq. [m]

Kalm ſays that it abounds in the woods of all North America; that the French call it *Cerfeuil ſauvage*, and make uſe of it in ſpring in green ſoups, like Chervil, and that it is univerſally commended in North America as a wholeſome antiſcorbutic plant.

4. Root annual. Radical leaves linear, ſuperdecompound, flat: leaflets ſeſſile, folded back and imbricate. Stem-leaves ſuperdecompound-pinnate, briſtle-ſhaped: thoſe which terminate the petiolar ſheath are trichotomous and longer than the others [n].

Stem a foot high, ſimple, erect, very ſlightly grooved: branches very few, at the top of the ſtem, or from the axils of the middle, not the lower leaves. Leaves uniform, triangular, tripinnate; leaflets ſetaceous-ſubulate, two or three lines in length, trifid or eared, ſeldom quite entire. Petioles of the radical leaves two inches long; of the middle ſtem-leaves an inch. Sheaths membranous at the edge, wider at the baſe, half-embracing; very much narrowed at the top, not two-lobed, running into the petiole. Umbels of two or three rays, half an inch long, remote; without any general involucre. Umbellets of eight to twelve rays, for the moſt part equal. The ſheaths of the middle and branch-leaves are often two-lobed. This plant has a fragrant aromatic ſmell [o].

Native of Portugal, Apulia and Egypt.

5. Root annual or biennial. Stems creeping, floating, round. Leaves alternate, unequally pinnate, with membranous ſheathing ſtipules embracing the ſtem: ſuch leaflets as are above the water are oblong, trifid, often pinnatifid; thoſe under water, eſpecially at any depth, are finely divided into capillary ſegments, as in *Ranunculus aquatilis*. The umbels are placed oppoſite to each leaf, juſt within the ſtipule, on longiſh peduncles, and conſiſt of only two partial umbels, without any general involucre. Each partial umbel has about five, white, ſlightly radiant flowers, with oval, entire, ſpreading petals; and for the moſt part a four-leaved involucre. Fruit elliptic, ſtriated [p].

Dr. Smith, in Engl. bot. ſuggeſted that this plant rather belongs to the genus *Hydrocotyle*; and in his Britiſh Flora he has removed it into that genus. Haller and Roth make it a *Sium*, as the old authors had done.

Native of the North of Europe, Britain, Germany, Switzerland and Dauphiné. It ſeems not to be unfrequent in wet places overflowed in winter, as well as ditches and pools. It flowers in may.

6. Leaves only radical, in bundles, ſhorter, pinnate: pinnas oppoſite, oblong; the firſt pair decompounded, the reſt not: leaflets with lanceolate pinnas, green, with a white membranaceous border, in bundles. Stem conſiſting of umbelliferous branchlets with awl-ſhaped bractes at the ramifications: branchlets divaricate. Umbels ſmall, erect. Involucres ſmall, awl-ſhaped. The leaves flouriſh in the ſpring, and after they wither away the ſtem grows up, and flowers in auguſt, in a manner leafleſs.—Native of Siberia, in the ſalts near the Wolga [q]. 2ſ

7. Native of Siberia, where it was diſcovered by Pallas.]

PROPAGATION AND CULTURE.

1, 2. Sow the ſeeds in autumn, in a moiſt ſhady ſpot of ground; or permit the ſeeds to ſcatter, and the plants will riſe without care.

3. 4. 6. 7. Sow the ſeeds as above. The plants require no other culture than to thin them where they are too cloſe, and keep them clean from weeds. They delight in a moiſt ſoil and ſhady ſituation, where the roots will continue ſeveral years.

*16. Sisym-

*See some leaves back

Digitized by Google

he believed it to be rather common throughout the iſle of Thanet [d].

β. S. Erucaſtrum of Gouan is probably a variety of this.

18. Root perennial and ſtrong. Stems ſeveral, ſix or eight inches high, ſpreading unbranched, round, ſmooth, for the moſt part deſtitute of leaves, except about the bottom. Leaves many, on longiſh ſtalks, rather fleſhy and inclining to a glaucous hue, pinnatifid; their lobes narrowiſh, diſtant, entire or toothed, having here and there a few briſtly hairs. Flowers large, in a corymb. Calyx tipped with hairs; its leaves but little expanded. Petals lemon-coloured veined with purple. Pods looſely ſpreading, not quite erect, beaked, obſcurely ſquare, ſmooth.—In a garden the ſtems become taller and leafy, ſometimes branched [e].

Native of Britain. Found in the iſle of Man, between the landing-place at Ramſey and the town plentifully: by Mr. Lawſon, in Sella fields, Seabank, Cumberland; alſo between Marſh-grainge and the iſle of Walney, but not plentifully. Near Abermeney-ferry in Angleſea, by Mr. Llwyd [f], who ſhewed it to Dillenius in 1726. He conveyed ſome plants to London, and planted them in the Eltham garden, where they flowered the year following in may [g]. Several perſons have found it ſince in Walney iſland. In Scotland, on ſandy coaſts in many places; as in the iſles of Bute, Skye and Arran, and in Cantire [h].

S. monenſe of Villars and Allioni, and n. 8. of Ger. prov. which Linneus had before him when writing the ſecond edition of his *Species Plantarum*, is the next ſpecies. It has ſmaller flowers than this, leſs evidently veined, and differs in its general aſpect [i].

19. This is very diſtinct from the preceding. The leaves are never pinnate, but only ſinuate and ſometimes almoſt quite entire, and altogether ſmooth. Pods very long (two inches,) compreſſed, and the valves have a raiſed longitudinal future through the middle, which gives them a ſquare appearance. Perennial.—Native of Provence, Dauphiné and Piedmont [k].

20. Root biennial. The whole plant ſmooth. Radical leaves petioled runcinate-pinnatifid, with the terminating lobe roundiſh-five-cornered, a little larger than the others. Stem upright, panicled at top with three or four racemes. Stem-leaves oblong, the lower runcinate pinnate at the baſe, the upper oblong blunt toothed very fine pinnatifid at the baſe. Flowers yellow.—Native of the Val d'Aoſt [l].

21. This has the appearance of *S. muralis* and *monenſis*, but the leaves, though ſmall and a finger's length, are lyrate altogether like thoſe of *Barbarea*, blunt and even. Scapes filiform, almoſt upright. Flowers yellow, not larger than thoſe of *Sophia*. Petals erect, blunt, ſcarcely twice the length of the calyx.—Native of the South of France and Sicily [m].

22. Root annual. Leaves radical, very many, lyrate, toothed as in *Taraxacum*, though ſcarcely an inch long, hiſpid all over with pellucid briſtles. Stem erect, more thinly hiſpid, with few branches, under which is an awl-ſhaped leaf. Calyxes even. Petals yellow, oblong, biggiſh, entire. Siliques oblong, ſwelling a little at the ſeeds [n]. Allied to the next, but differing in having yellow flowers [o].

Native of Spain and Italy. Introduced in 1770, by Monſ. Richard. It flowers in july [p].

23. Root annual. Radical leaves very many, lanceolate-lyrate, hiſpid on both ſides with branching bifid or trifid hairs. Stem-leaves lanceolate, toothed, hiſpid like the others. Stem rough with a few ſimple hairs. Calyxes ſmooth. Corollas white tinged with pale violet [q]; or quite white or all purple.

Native of Sweden, Germany, Switzerland, Auſtria and Carniola.

24. Root annual. Stem erect, round, a foot high, very ſlender, and ſcarcely branched, having a few hairs ſcattered over it below, ſmooth above. Root-leaves narrow-lanceolate, with four ſtout teeth ſtanding out forwards, hiſpid with white ſimple hairs ſome longer others ſhorter. Stem-leaves fewer, lanceolate-linear, not toothed. Peduncles filiform, longer than the flower.

Native of Spain, in the kingdom of Valencia and about Madrid [r].

25. Root annual or biennial. Leaves radical, ſpreading in a ring, abundant; the interior ones leſs, a ſpan long, runcinate, like thoſe of Shepherd's-purſe; the upper ſurface, eſpecially the edge muricated with warts, or ſcattered mucronate tubercles, having a tranſparent point. Theſe tubercles for the moſt part diſappear when the leaves are more advanced. They are alſo rugged on the lower ſurface. Pinnas oppoſite, wider at the baſe, toothed, preſſed cloſe by pairs at the upper baſe. The firſt year it is ſtemleſs; the ſecond year it produces a ſtem; it flowers in both. Scapes erect, even, with remote ſcattered ſtrigæ, panicled, a foot high. Pedicels remote, ſpreading, ſtiff, longer than the flower, a day or two before flowering (which is ſingular) recurved; erect. Calyx cloſed, even, pale, gaping with a more ſwelling baſe. Petals obovate, obtuſe, quite entire, diſtant, twice as long as the calyx, yellow. Nectareous glands four, two oppoſite between the longer ſtamens, and the inner leaflets of the calyx, awl-ſhaped, longer than in moſt of this claſs. Silique round, cylindrical, even, ſwelling a little at the ſeeds.—Native of Braſil [s].

26. Root annual. Stems half a foot long and almoſt trailing. Leaves green, winged, and the leaflets ſometimes cut. Flowers ſmall and yellow. Siliques about half an inch long, rather thick in proportion to the ſize of the plant, round, rude and villoſe [t].

Native of the South of France and marſhes about Eſtremadura. Introduced in 1778, by Monſ. Thouin. It flowers in may and june [u].

27. Root annual. Radical and lower leaves pinnate, with the pinnas linear and groſsly toothed: ſtem-leaves pinnate, with the pinnas linear, acute, quite entire. Flowers yellow. Siliques an inch and half long, ſmooth. It reſembles the preceding.

28. This reſembles the following ſpecies, but the ſtem is ſhrubby, the leaves are hoary, the leaflets oblong, and the petals bigger than the calyx.

Native of the rocks of Teneriffe [x]. Found there by Mr. Francis Maſſon, and introduced in 1779. It flowers from may to ſeptember [y].

29. Root annual, ſmall, tapering. Stem a foot and half or two feet high, upright, round, much branched and very leafy. Leaves alternate, ſpreading, three inches long and more, two inches broad, very finely divided; doubly pinnate, or perhaps more properly pinnatifid, for the principal and partial diviſions are all confluent; the laſt ſegments are lanceolate, acute, entire, more or leſs evidently hairy; the terminating ones largeſt. Flowers in corymbs, very ſmall, numerous, frequently more than a hundred in a ſingle corymb. Petals pale yellow, ſo minute as to be almoſt hidden by the calyx, which has nearly as much colour as themſelves. The corymb ſoon grows out into a very long ſpike of ſlender pods, which ſtand erect on ſpreading pedicels: they are about half an inch in length, ſo obſcurely four-cornered as to ſeem round, and ſwell out a little where the ſeeds are. Seeds numerous, ſmall, roundiſh, ſmooth, yellow or reddiſh.

Flix-weed is ſo named, from the quality attributed to it of curing immoderate laxity of the bowels. It is not uncommon in moſt parts of Europe, on walls, among rubbiſh, about church-yards, waſte ground, hedges and dunghills; flowering in june, july and later, and ripening its ſeeds in auguſt and ſeptember. The pods retain the ſeeds all winter, for the food of ſmall birds.

According to Linneus, ſheep and kine eat the plant, horſes and goats are not fond of it, and ſwine refuſe it. With us it ſeems ſeldom to be cropped by cattle, except from wantonneſs. The force of gunpowder is ſaid to be augmented, by mixing a tenth part of the

[d] Linn. tranſ. 6. 389. [e] Hort. elth. [f] Ray ſyn. [g] Engl. bot. [h] Lightfoot. [i] Engl. bot. [k] Willdenow. [l] Idem. [m] Linn. ſpec. [n] Idem. [o] Willdenow. [p] Hort. kew. [q] Linn. ſpec. [r] Linn. ſpec. [s] Linn. mant. & ſyſt. [t] Villars. [u] Hort. kew. [x] Willdenow. [y] Hort. kew.

Digitized by Google

ſeeds with the other ingredients. The plant is ſometimes preſcribed in dyſenteries and hyſteric caſes; and the ſeeds are given to deſtroy worms [z].

30. Root perennial. Stems a ſpan high, upright, very finely tomentoſe, ſeveral from a ſomewhat woody root. Leaves becoming hoary; thoſe next the root pinnate, with obovate pinnas moſt commonly two-parted, the upper ones confluent: ſtem-leaves pinnate, with the pinnas lanceolate, quite entire, obtuſe, attenuated at the baſe, the upper ones confluent. Petals bigger than the calyx, white. Siliques linear, round, even, erect.—Native of Siberia, by the lake Baikal.

31. Root annual. Plant a ſpan high. Stem upright, branched. Leaves pubeſcent, ſomewhat fleſhy; lower ſubbipinnate, upper ſimply pinnate, with the pinnas diſtinct, linear-filiform, obtuſe. Flowers pale violet.—Native of Barbary, near Caſſa, in ſands [a].

32. Lower leaves flaccid, runcinate, ending in arrow-pointed lobes. Stalks three or four feet high, with linear leaflets. It branches out greatly on every ſide. Flowers ſcattered at the ends of the branches. Pods very long, ſlender, ſmooth; filled with ſmall yellowiſh ſeeds. [Annual. Native of Siberia, Armenia, and Auſtria.—Cultivated by Mr. Miller in 1768. It flowers in auguſt [b].

33. This is very like the preceding, but differs in having the leaves rugged at the edge, and eſpecially in having the ſiliques much narrower and ſhorter, filiform, bent in and ſpreading a little, but not ſpreading wide and divaricating. Annual. Suppoſed to be native of Thuringia [c].

34. This is a biennial plant, or annual. Stems three or four feet high, branched, erect, ſlightly angular. Lower-leaves runcinate-pinnatifid with toothed lobes, the lower of which are diſtinct and remote, the upper confluent; little hairy, except along the nerves and margin, which have white hairs: they have the taſte of Muſtard. Calyx and corolla yellow. Stigma headed, perforated, large. Between the piſtil and each ſhorter ſtamen is a large gland. Siliques ſpreading, very narrow, ſwelling a little, ſmooth [d].

Native of Hungary. Introduced in 1787, by Mr. Zier. It is annual, and flowers in auguſt [e].

35. Leaves ſmooth, pinnatifid; ſegments oblong, toothed at the end, the terminating one very large, rhomb-ſhaped, gaſh-toothed. Racemes long. Flowers ſmall, white. Siliques linear, an inch long and more, ſpreading horizontally, almoſt ſeſſile.—Native of Tunis near Kerwan, in ſandy places [f].

36. Root annual, fuſiform, ſmall. The whole plant perfectly ſmooth, with the biting taſte of Muſtard. Stem upright, from one to two feet high, round, ſhining, here and there purpliſh, ſomewhat flexuoſe, leafy, not ſtriated or grooved, branched at top, and often quite from the bottom. Leaves alternate, except the uppermoſt runcinate-pinnatifid, unequally and variouſly cut, toothed or ſerrate, petioled, ſpreading and flaccid, the lobes for the moſt part acute, the end one larger and longer: the uppermoſt leaves are haſtate or ſimply lanceolate, entire or having one or two teeth towards the baſe. Flowers in corymbs, ſoon lengthened out into long ſpikes. Calyx ſpreading and yellowiſh. Corolla ſmall, yellow; petals longer than the calyx, obtuſe, oblong, ſpreading widely. Siliques numerous, ſlender, nearly round, about two inches long, on ſhort pedicels. Seeds very ſmall, pale yellow; and being a little protuberant, the pods have the appearance of being finely jointed; a character which readily diſtinguiſhes this plant [g].

Native of many parts of Europe, in corn fields; with us on dry banks, old walls, and among rubbiſh; flowering from june or july to auguſt or ſeptember. Mr. Ray obſerved it at Faulkbourn in Eſſex, and on the walls of Berwick upon Tweed; though ſcarce in many parts of Britain, it is frequent in the neighbourhood of London. After the great fire in 1666, it came up in ſuch abundance on the ruins, that in many places it might have been mowed like a field of corn [h].

37. Like the preceding, but pubeſcent and ſomewhat hoary all over, and the flower paler. Annual.—Native of Germany, Auſtria and Italy, in dry places [i].

38. Root annual, fuſiform. Stem upright, two or three feet high, often variouſly flexuoſe, round, ſlightly ſtriated, hiſpid. Branches alternate. Leaves like thoſe of *Eryſimum officinale*, alternate, petioled, wider below, and narrowing gradually to the top into a linear lobe, pinnatifid, the lower pinnas lanceolate-linear, bluntiſh, toothletted, towards the upper part gradually leſs pinnatifid, and at length toothletted, ſomewhat hairy above and below, ciliate and roughiſh about the edge. Petioles channelled within. Petals blunt, twice as long as the calyx, yellow. Siliques in a looſe raceme [k].

Native of Germany, Auſtria, Pruſſia, and France. Introduced in 1787, by Mr. Zier. It flowers in auguſt [l].

39. Root annual. Stem erect, grooved, having a few reflex hairs eſpecially towards the baſe. Leaves almoſt like thoſe of *Pedicularis Sceptrum*, pinnatifid, with blunt pinnas obtuſely and groſsly toothed, the lower ones gradually ſmaller; the laſt pair embracing the ſtem like ſtipules. Flowers yellow. Siliques obtuſely four-cornered, ſmooth.

Native of Switzerland, and diſtinct from *Braſſica Erucaſtrum* [m].

40. An annual plant, native of the Levant. Introduced in 1775, by Chevalier Murray. It flowers in july [n].

41. Root perennial. Plant very like to *Eryſimum Barbarea*, but inſipid. Stem angular. Radical leaves quite entire, cordate-ovate [o].—Native of the Levant. Cultivated by Mr. Miller in 1759.

42. Stem-leaves linear-lanceolate remotely and groſsly toothed. It is a perennial plant, native of the Cape of Good Hope [p].

43. Stems a palm or a foot in height, even. Both root and ſtem-leaves pinnate, even, brittle: leaflets oblong, ſerrate or toothed, at the top of the petiole often confluent. Raceme oblong. Flowers on long peduncles. Petals yellow, obovate, entire, large. Calyx even. Siliques remote.—Native of Spain and Portugal [q].

44. Native of New Zealand.

45. Root perennial. Stem herbaceous, a palm high, roundiſh, ſmoothiſh, ſimple, dichotomous towards the top, flowering branchlets erect. Root-leaves in tufts; ſtem-leaves alternate, all pinnate, compoſed of three or four pairs of leaflets, and an odd one, larger than the reſt, kidney-form, ſomewhat crenate, ſeldom cut; the lateral ones gradually ſmaller, roundiſh, oblique, all ciliate, ſubſeſſile, ſomewhat remote. Floral leaves pinnatifid. Flowers white, biggiſh in proportion to ſo ſmall a plant. It is allied to the preceding, but different.

Native of Terra del Fuego, in wet places, almoſt under the ſnow itſelf [r].

46. Root perennial. Leaves pubeſcent on both ſides and much veined. Anthers, when they have ſhed their pollen, violet-coloured [s]. Siliques ſpreading very much. It varies ſometimes with the leaves quite entire [t].]

Stems branching, near three feet high. Leaves about three inches long, and an inch broad, of a deep green, alternate. Flowers in looſe terminating ſpikes, ſmall and yellow, appearing in june. The pods ripen in auguſt.

[Native of Germany, Auſtria, Switzerland, and Italy.—Cultivated 1658, in the botanic garden at Oxford [u].

47. Stem ſomewhat branched, upright. Leaves hiſpid, lanceolate, gaſh-toothed, attenuated at the baſe into the petiole. Flowers yellow. Siliques linear, on long peduncles, pendulous.—Native of Barbary, near Caſſa, in ſands.

Digitized by Google

48. Root biennial. Stem erect, branched, divaricate. Leaves alternate, bluntly toothed especially towards the top, and sometimes quite entire. Racemes long. Flowers yellow. Siliques filiform, short, bowed. Native of Spain.

49. Root annual. Plant a finger or a span in length, hoary-pubescent all over. Stem branched at the base. Radical leaves blunt, runcinate; stem-leaves embracing, sagittate, toothed. Racemes very long. Flowers yellow. Siliques linear, half an inch long, erect or a little spreading.—Native of the northern parts of Persia.

50. Root annual. Plant very smooth, glaucous. Leaves sharpish. Flowers small, white. Siliques thick, erect or spreading.—Native of salts in Siberia[x].

51. Root annual. Stem a finger's length. Leaves linear, smooth, bluntish. Racemes terminating, pubescent, viscid. Flowers biggish, white. Siliques linear. Native of Siberia[y]. It varies, according to Gmelin, with yellow flowers[z].

52. Root annual. Stem about a foot high, almost upright, flexuose, angular, even, somewhat branched below. Leaves wide-lanceolate or lanceolate-ovate, naked, much pointed, petioled except the upper ones. Racemes terminating and axillary, longer than the leaves. Flowers small, white, with the petals scarcely longer than the calyx. Siliques round, very slightly bowed.—Native of the East Indies[a].

53. Plant a palm high, sometimes but seldom scarcely a span, branched, erect, hispid all over except the peduncles and siliques. Leaves an inch long, thickish, unequally toothed, veinless, ending in the petiole. Pedicels declining, short. Siliques length of the pedicels, linear, remote. It approaches to Gouan's *Sisymb. Erucastrum*, but differs in the form of the leaves, its hairiness, size, and in having an upright leafy stem[b].—Native of Egypt.]

PROPAGATION AND CULTURE.

1. Water Cress is generally gathered for a spring salad in ditches or other standing or slow-flowing waters; and is also cultivated to supply the London markets. This may be easily done, by taking some of the plants from the places of their natural growth early in the spring, being careful to preserve their roots as entire as possible, and plant them in mud, letting water in upon them by degrees. They will soon flourish, and spread over a large compass; they should not be cut the first season, but suffered to run to seed; for the seeds will fall into the water, and furnish a sufficient supply of plants.

Where the water is so deep that it is not easy to plant it, procure a quantity of plants in july, just as their seeds are ripening, and throw them on the surface of the water, where they are designed to grow: the seeds will ripen, fall to the bottom and take root there without any farther care.

2, 3, 4. The other Water-Rockets may be propagated in the same manner, or by seeds sown on the banks of ditches or streams.

5, &c. Those which grow on dry land may easily be propagated, by sowing the seeds in autumn, or by permitting them to scatter; thinning them, and keeping them clean from weeds. Most of them prefer a dry soil, and some flourish best on walls.

10. Siſyrinchium narciſſoides.
Cavan. diſſ. 6. 347. *t.* 191. *f.* 3.
Galaxia narciſſoides. *Lin. ſpec. ed. Willd.* 3. 583.
Stem erect round, ſpathe two-valved ſubquadriflorous, flowers drooping, leaves linear-enſiform.

DESCRIPTIONS, *&c.*

1. Scape covered with oblong acuminate alternate ſpathes. There is only one procumbent linear acuminate leaf, twice as long as the ſcape; and one large terminating flower. Corolla yellow on the outſide, marked in the middle of the three outer petals within with a large green ſpot; petals linear-oblong acute.—Native of the Cape of Good Hope.

2. Very like the preceding, but differs in having the ſcape much higher and ſubtriflorous, having one flower upon each branch; the leaf not procumbent but hanging down; the corolla larger and unſpotted, red or pale yellow.—Native of the hills near the Cape, where it is very abundant.

3. Root bulbous. Root-leaves as well as thoſe of the ſcape lanceolate and attenuated to both ends, plaited and ſtriated. Spathe terminating, three-flowered. Corolla an inch and half in diameter, yellow; petals obovate, very blunt.—Native of Peru [c].]

4. Root fibrous, from which ariſe ſome ſtiff ſword-ſhaped leaves, four or five inches long and half an inch broad, of a dark green colour; from among theſe comes out the ſtalk (ſcape) ſix inches high; it is compreſſed, and has two borders or wings running the whole length, and three or four ſpear-ſhaped leaves embracing it; theſe grow erect, and are hollowed like the keel of a boat. The ſtalk is terminated by a cluſter of ſix or ſeven flowers, on ſhort peduncles, and incloſed in a two-leaved, keel-ſhaped ſheath, before they open; they are of a deep blue colour with yellow bottoms; when fully expanded they are an inch over.—Native of Bermuda.

[Height from a foot to a foot and half. Leaves like thoſe of the Iris, but ſmaller. Stem or ſcape compreſſed and ſtriated like the leaves, only firmer and ſomewhat thicker in the middle, and branched a little at the top. Sheath ſimple or double. Flowers four, five or more, on ſhort peduncles: the three inner petals are ſomewhat narrower, of a violet purple colour within, with yellow crenate ſpots at the baſe, and marked with deeper-purple ſtreaks; the outſide is of a pale violet, with greeniſh-yellow claws: the petals are blunt, ending ſuddenly in a point, which is ſhorter than in the next ſpecies. The capſules alſo are leſs blunt and rounded than in that, the flowers are larger and of a different colour, and the whole plant is bigger [d].]

5. Root perennial, fibrous, from which ariſe many very narrow ſpear-ſhaped leaves, about three inches long, and ſcarcely an eighth of an inch broad, of a light-green colour. Stalks about three inches high, very ſlender, compreſſed and bordered, having ſhort, narrow, ſword-ſhaped, embracing leaves: they are terminated by two ſmall pale-blue flowers, incloſed in a two-leaved ſheath, upon longer peduncles than thoſe of the preceding; flowering about the ſame time. The leaves, ſtalks and flowers of the fourth are three times as large as in this, and the ſheath incloſes ſix or ſeven flowers; whereas this has rarely more than two, and theſe expand only for a ſhort time in the morning, but the others continue open the whole day.

[Mr. Curtis alſo remarks, that it is far more diminutive than the Bermudiana, with much ſmaller flowers, of a paler blue colour; a much hardier plant, producing abundance of flowering-ſtems in june and july.

Dillenius remarks, that the petals do not end ſo bluntly, but more gradually in a longer point; that they have fewer ſtreaks and thoſe only towards the baſe; and that they are of the ſame colour both within and without.

Native of Virginia and other parts of North America. Cultivated in 1693, by Mr. Jacob Bobart [e].

6. This is a ſmall plant, two inches high. Leaves linear-acuminate. Spathe two-valved as long as the flowers or a little ſhorter. Flowers two or three, very ſmall, with linear, acuminate petals.—Native of Peru.

7. This very much reſembles *S. Bermudiana*, but the ſtem is two feet high. The leaves are twice as wide, folding with five or ſix nerves. Glumes and flowers numerous in a terminating bundle, ſcarcely larger than thoſe of Bermudiana. Style trifid beyond the middle. It is very different from *Moræa plicata*, with which it has been confounded.——Native of Braſil [f].

8. Root tuberous. Stem two feet high, erect, ſmooth, much branched, many-flowered. Leaves ſword-ſhaped, pointed, entire, ſlightly ribbed, glaucous, ſmooth, with a little membranous border: thoſe next the root equitant, ſtem ones alternate, embracing. Flowers in terminating and lateral heads, a little drooping, very numerous but ſhort-lived, with ſcarcely any ſmell, pale yellow ſtreaked with purple, the colours ſtrongeſt on the outſide. Spathes of a ſingle leaf, concave, carinated, acute, ribbed, with a membranous margin, the external one largeſt, but ſhorter than the flowers, and enfolding them along with the interior ſpathes which are much ſmaller, and one to each flower. Peduncles about the length of the outer ſpathe, triangular, ſingle-flowered. Petals obovate, obtuſe with a little point, at the baſe ſlightly connected, and ſpotted within, ſomewhat concave, with a ſpreading border, the three outer a little ſmaller. Filaments ſhorter than the corolla, united into a tube for more than half the length, ſpreading in the upper part, ſmooth: anthers verſatile, ſmall. Germ roundiſh, ſmooth, green: ſtyle length of the ſtamens, three-cleft in the upper part: ſtigmas notched. Capſule roundiſh, three-lobed; valves carinated at the back.

Sent from Italy by P. Stephens, Eſq. to Mr. Forſyth. It thrives and flowers abundantly in the open ground, but its native country we have yet to learn [g]. Willdenow makes it the ſame with *S. ſpicatum* of Cavanilles, which is a native of Mexico; but if it comes from ſo hot a country, it is ſingular that it ſhould thrive and flower in England in the open ground.

9. Root fibrous. Scape compreſſed, branched at the top, ſtriated, ſmooth, erect, two feet high and more. Radical leaves very many, diſtich, linear, attenuated at the top, ſtriated, ſmooth, erect, almoſt the length of the ſcape, on which a ſingle leaf, or a few, ſimilar. Flowers on the branchlets, terminating, umbelled, ſmall, white, about three or four. Spathes lanceolate, ſhorter than the peduncles; which are capillary and an inch long [h].

Native of New Zealand [i]. Thunberg has made it a *Moræa*, and Willdenow, a *Ferraria*. The former of theſe differs in having the ſtamens ſeparate; the latter in having the ſtyle divided at the top into ſix parts. Mr. Saliſbury unites the three genera into one. And, as Dr. Smith obſerves, in an order ſo natural as this, it is very difficult to find generic characters that ſhall be ſtable, and not ſet aſide by new ſpecies.

10. This has the habit of a *Narciſſus*, with the flower of a *Galaxia*, to which genus Willdenow has removed it from this in which it was placed by Cavanilles. It differs only in having a two-valved ſpathe; and has nothing in common with the genus *Siſyrinchium*, except the ſpathe and cohering ſtamens [k]. The corolla is white, but there is a fine variety, with the flowers ſtreaked longitudinally within and without with deep purple.—Native of the ſtraits of Magellan [l].]

PROPAGATION AND CULTURE.

4. 5. Theſe plants are propagated by ſeeds and alſo by parting of their roots; if they are raiſed from ſeeds, theſe ſhould be ſown in autumn ſoon after they are ripe, upon an eaſt-aſpected border, where they may have only the morning ſun: the beſt way will be to ſow them in drills at three or four inches diſtance, covering them about half an inch with light earth. In the ſpring the plants will appear, when their leaves will have much reſemblance to Graſs, therefore care ſhould be taken that they are not pulled up as weeds by thoſe who clean the ground. During the firſt ſummer they will require no other care but to keep them clean from weeds, unleſs the plants ſhould come up ſo cloſe as not to have room to grow, in which caſe, part of them ſhould be drawn out to give room to the others, and theſe may be planted in a ſhady border at three inches diſtance, where they may remain till autumn, when they ſhould be tranſplanted to the places where they are to remain, and the following ſummer they will flower. Theſe plants love a ſhady ſituation and a ſoft, loamy, undunged ſoil.

The time for tranſplanting and ſlipping off the old roots is early in autumn, that they may get good roots before winter. The fifth is ſo hardy as to thrive in the open air in England, and is very rarely injured by cold.

[The Bermudiana (n. 4.) is a tender plant, and requires the protection of a green-houſe or glaſs-caſe. The anceps (n. 5.) is a hardy perennial, adapted to the open border, in which it will grow readily [m].

The firſt and ſecond ſpecies muſt be kept in the dry ſtove, and the reſt in the bark-bed. They may all be increaſed by the root.

Leaves tripinnate, petioles and peduncles rugged.

19. Sium villosum. *Villose-leaved Water Parsnep.*
Lin. spec. ed. Willd. 1. 1435. *Thunb. prodr.* 51.
Leaves tripinnatifid, segments ovate gash-serrate villose.

DESCRIPTIONS, *&c.*

1. Stem herbaceous, erect, a foot high, scarcely branched, slender, round, smooth, slightly streaked. Leaves all simple, very narrow, a little wider and somewhat sheathing at the base, very smooth; the lower ones four inches long or a little more; stem-leaves remote. Peduncles lateral and terminating, few, remote. Involucre five-leaved: leaflets awl-shaped, stiffish, shorter than the umbel. Involucrets length of the umbellet. Umbel small, five-rayed. Umbellets eight or ten-flowered. Seeds oblong, streaked, small, smooth. Styles permanent, divaricating.—Native of the Cape of Good Hope [a].

2. Broad-leaved Water-Parsnep is one of the largest among the umbelliferous tribe. Its perennial root, creeping among mud and gravel, throws up round, hollow, upright, smooth, deeply furrowed stems, four, five, and sometimes even six feet in height; clothed with alternate leaves, composed of seven, or sometimes nine, opposite, sessile, ovate or lanceolate, veined, smooth leaflets, varying much in breadth, but always very equally and neatly serrate; in which respect they differ materially from *S. angustifolium*, as well as in being much longer. Mr. Hudson well remarks, that such as grow under water are often laciniated. Umbels solitary, terminating and lateral, erect, large, flattish, many-flowered. Involucre of many, lanceolate, unequal leaflets, sometimes lobed and often serrate. Involucrets ovate, short. Petals acuminate, inflex-cordate, white, uniform, but a little unequal in size. Fruit small, striated.

It is a plant of an acrid poisonous quality, particularly the roots [c].

Native of many parts of Europe, and of Siberia. It is not of rare occurrence in rivers and fens throughout England. Mr. Doody observed it in the ditches between Rotherhithe and Deptford. Northfleet in Kent. In Cambridgeshire, the Isle of Ely, and Norfolk, not uncommon. Bedfordshire. Oxfordshire. Moors near Pitchcroft, Worcester. Pool in Nottingham-park. In all the ditches near a pool of water called Brayford, near Lincoln, &c. In the Stour, Froome and Piddle, Dorsetshire. First observed in England in *Phyt. brit.* It flowers in july and august.

3. Root perennial, creeping, so as to occupy much space. It is smaller and weaker than the preceding. Stem upright, with whorls of radical fibres in its lower part under water, round, striated, smooth, much branched above, leafy. Leaves alternate, simply pinnate: leaflets numerous, sessile, the lowermost pair remote from the rest, and smaller, at least in the lower leaves, in which also the leaflets are obliquely heart-shaped at the base; otherwise they are lanceolate, often so deeply lobed as to become hastate, pointed, very irregularly and sharply serrate, and very smooth: the end one commonly trifid. Umbels solitary, opposite to each leaf, peduncled, erect, hemispherical, peduncles divaricated, somewhat shorter than the adjoining leaf. General involucre of many drooping leaves, which are occasionally entire, serrate or pinnatifid; the partial ones ovate and more entire. Calyx of five minute teeth, scarcely visible. Petals white, uniform and almost equal. Fruit small, smooth, slightly ribbed, ovate [b].

Dr. Withering remarks, that this and the *latifolium* are readily distinguishable by the specific characters, but that the trivial names of *broad* and *narrow* leaved are ill appropriated because tending to mislead, for neither the leaves nor leaflets of the latter are narrower than those of the former, and if there is a difference it is generally the reverse of what the trivial names would lead us to expect.

It was originally considered by Linneus as a variety of the *latifolium*, and was first established as a distinct species by Mr. Hudson [d]. It was however considered as distinct by Miller, Ray, Rivinus, Morison, and the old botanists in general.

Native of most parts of Europe. Frequently found in Britain, in ditches and rivulets; in Cambridgeshire, Norfolk, Bedfordshire, Oxfordshire; Dorsetshire in the Stour; Kingston Pool, near Stafford; King's Park, meadows and ditches near Edinburgh. It flowers in july and august.

[a] Vahl. [c] Smith brit. & engl. bot. [b] Idem. [d] Engl. bot.

Digitized by Google

Doody conſidered it as a ſpecific in ſcrophula, eſpecially the expreſſed juice [r]: and Dr. Withering obſerves, that it certainly poſſeſſes active properties which ought to be inquired into.

4. Root perennial, creeping. Stems procumbent or floating, often creeping, various in length, branched, round, hollow, ſlightly ſtriated, ſmooth, leafy. Leaves unequally pinnate: leaflets from five to nine, ſeſſile, ovate, all neatly and equally ſerrate; the odd one largeſt, and ſometimes united with the neighbouring pair. Umbels lateral, each ſingly oppoſite to a leaf, nearly ſeſſile, compoſed of from five to ſeven divaricated rays. Umbellets bearing twelve flowers or more. General involucre one-leafed; often entirely wanting: partial, of ſeveral ovate concave leaflets, as long as the pedicels. Flowers ſmall, greeniſh white, with ſlight traces of a calyx. Fruit ovate [s].

Native of many parts of Europe. Common in Britain, in ditches and rivulets; flowering in july and auguſt.

This plant is not admitted into the Materia Medica of any Pharmacopœia, except that of London, where it is received in the character of an antiſcorbutic, or rather as a corrector of acrid humours, eſpecially when manifeſted by cutaneous eruptions and tumours in the lymphatic ſyſtem. The beſt proofs of its efficacy are from Dr. Withering.—A young lady, ſix years old, was cured of an obſtinate cutaneous diſeaſe, by taking three large ſpoonfuls of the juice twice a day: and I have repeatedly given to adults, ſays the doctor, three or four ounces every morning, in ſimilar complaints, with the greateſt advantage. It is not nauſeous, and children take it readily if mixed with milk. In the doſe I have given it, it neither affects the head, the ſtomach, nor the bowels [t].

This plant therefore, if it ſhould be eaten for Water Creſs, does not ſeem to be very dangerous, or to require all that caution which Mr. Miller preſcribes. For the difference between them ſee the article *Siſymbrium Naſturtium*; and the 13th and 21ſt plates to the letters on the Elements of Botany.

5. Stems proſtrate, creeping, round, ſtriated, leafy. Leaves unequally pinnate: leaflets roundiſh, ſometimes wedge-ſhaped, tooth-gaſhed and variouſly lobed, veined; the end one three-parted. Umbels oppoſite to a leaf, peduncled. Umbellets few, divaricating, many-flowered. Involucres and involucrets many-leaved, ovate, nerved, bent down. Calyx indiſtinct. Fruit roundiſh, compreſſed [u].

According to Hoſt, the leaflets are oppoſite, ſeſſile, ovate-roundiſh, unequally ſerrate, the end one, for the moſt part, more or leſs three-lobed. Involucres and involucrets ſix-leaved or nearly ſo. Willdenow remarks, that this plant reſembles *Siſon inundatum*, but that the leaves are wider, blunter and uniform; and that the umbels are four-rayed, with a general involucre.

Native of Bohemia in wet meadows, and of Auſtria on the banks of the Danube. In England, it has been found in Cambridgeſhire, on Coldham common near Cambridge, by Mr. Relhan; on Bullington-green, and Cowley-bottom, near Oxford, by Dr. Sibthorp; on Goldington-green, and Stevington-bogs, in Bedfordſhire, by Dr. Abbot; in wet places in the ſouth of Scotland by Mr. Dickſon; and at Fiſkerrow, five miles from Edinburgh, and in abundance on the moiſt parts of Guillon Links, Eaſt Lothian, by Dr. Hope. It flowers from june to auguſt.

6. Root perennial, conſiſting of ſeveral oblong tubers, tapering to a point. Stem from twelve to eighteen inches high, erect, round, ſtriated, ſmooth, little branched and almoſt naked. Leaves moſtly radical and very remarkable, conſiſting of a ſimple rib, along which are arranged pairs of deeply cloven leaflets, the numerous ſegments of which are linear, acute, extremely narrow, pointing in all directions ſo as to form whorls, and that as truly as the flowers do in the Mints and other whorled plants properly ſo called; for thoſe grow only on two ſides of the ſtem, though they ſeem to embrace it all round. Umbels terminating, erect, of eight or ten rays, with a general involucre of five or ſix ovate, deflected, ſhort leaflets. Partial umbels more denſe, and nearly flat, with ſimilar involucres of more numerous leaflets. Calyx indiſtinct. Petals white, inflex-cordate, uniform and nearly equal. Fruit ovate-roundiſh, ſlightly compreſſed, deeply furrowed, crowned with the ſhort recurved ſtyles. Seeds ſlightly, but not pleaſantly aromatic [x].

On account of its many-rayed umbels, many-leaved involucres and involucrets, and cordate petals, Dr. Smith has removed this plant from the genus *Siſon* to this of *Sium*, to which it ſeems more properly to belong.

Native of Germany, France, the Pyrenees, and Britain, in moiſt meadows in the weſtern parts of Scotland and Wales; in the latter, as far as I know, it was firſt obſerved to grow abundantly about St. David's, by the late Canon Holcombe; or in Glamorganſhire, by the late Rev. Sir John Cullum, Bart. and by Mr. Pennant in almoſt every moiſt meadow in Caermarthenſhire and Pembrokeſhire abundantly. In Scotland it was firſt found by Dr. Houſtoun in moiſt meadows about Greenock plentifully: and ſince, in many like places it has occurred in Nithſdale and Galloway, and alſo in Annandale, particularly in the meadow between the farm-houſe of Stank in Ruthwell, and the bathing-place on the ſhore, by Dr. Burgeſs. It has alſo of late been diſcovered in the Iſle of Man, by the Rev. Mr. Davies, of Beaumaris in Angleſey [y]. In my herbarium there is a ſpecimen ſent by Houſtoun, and in the paper that accompanies it he ſays, that it grows plentifully near Greenock, and a village about two miles thence called Gourack; he remarks, that it has roots of two ſorts, the one bulbs like thoſe of Aſphodelus or Oenanthe, the others fibrous and creeping, ſomewhat like thoſe of the common Dog-graſs.]

7. The root of the common Skirret is compoſed of ſeveral fleſhy tubers as large as a man's little finger, and joining together in one head. The lower leaves are pinnate, having two or three pairs of oblong leaflets terminated by an odd one. The ſtalk riſes a foot high, and is terminated by an umbel of white flowers, which appear in july, and are ſucceeded by ſtriated ſeeds like thoſe of Parſley, which ripen in autumn.

[Our Engliſh name *Skirret* ſeems to be a corruption from the old name *Skirwort*. *Skir* may be corrupted from the barbarous latin *Chervillum*, the Spaniſh *Cherinia*, or the French *Cherui*.

β. Sium Ninſi of Linneus and Thunberg is the ſame plant, or at moſt a variety of our Skirrets. Linneus took it up from Kæmpfer's figure, which certainly repreſents *Sium Siſarum*. It is probable that the Japoneſe, being impoſed upon by the Chineſe, have taken this for the plant which furniſhed the Ginſeng: but we are now certain, from the figure drawn by Father Jartoux, on the ſpot where this famous root is collected, that it is the root of *Panax quinquefolium*. See his figure in vol. 10. of Lettres edifiantes, copied in Philoſ. tranſ. vol. 28. t. 5. and in Deſcription de la Chine par du Halde, fol. edit. vol. 2. p. 154 [z]. See alſo Panax quinquefolia in this Dictionary.

Loureiro deſcribes the ſtem as three feet high, almoſt upright, round, ſtriated, almoſt ſimple. Upper leaves ternate, ſerrate-gaſhed, ſmooth. Flowers white; general and partial umbels many-leaved, entire. Seeds ovate, ſtriated.—Native of China and Cochinchina, in watery places.

It appears from Gerarde's herbal that it was cultivated here in 1597 [a].] Formerly the roots were more uſed than they are at preſent; being eſteemed wholeſome and nutritive, but flatulent: their ſweet taſte is diſagreeable to many palates. [They were eaten boiled, and ſtewed with butter, pepper and ſalt; or rolled in flour and fried; or elſe cold with oil and vinegar, being firſt boiled [b].

8. Stem ſtiffiſh. Leaves unequally pinnate, with

[r] Ray ſyn. [s] Smith brit. & engl. bot. [t] Woodville. [u] Smith ex Linn. fil. [x] Smith brit. & engl. bot. [y] Lightfoot. [z] Dryand. in Linn. tranſ. [a] Hort. kew. [b] Parkinſon.

five

five or six pairs of leaflets; which are lanceolate, ſtiffiſh, and have a few teeth towards the top. Petioles channelled. Flowers ſmall.

Native of Virginia[a]. Introduced in 1774, by Mr. William Young. It flowers in july and auguſt[d].

9. Stem erect, flexuoſe, branched at top. Leaves pinnate, ſmooth; the loweſt largeſt: pinnas of different ſhapes, oblong, ovate, entire, gaſhed, ſpreading: upper ones very ſmall, with lanceolate entire leaflets. Umbels terminating the branches.

Native of Japan, in the iſland Nipon, flowering in june[e].]

10. Roots creeping, and ſpreading very far under ground, thick, fleſhy, and taſting like thoſe of Eryngo. The leaves are divided into linear ſegments, and their baſe embraces the ſtalks, which riſe two feet high, and are terminated by large flat umbels of white flowers; theſe appear in july, but the ſeeds do not often ripen here.

[General involucre eight-leaved bent back; leaflets linear, entire: partial, ſeven or eight-leaved. General umbel of fifteen; partial of about ſixteen rays[f]. Fruit ſmall, ovate-oblong, ſtriated, crowned with the permanent calyx, and within that by a tubercle bearing the ſtyle and fenced round with ſmall ſcales. Seeds ſemicylindrical, ſcored on one ſide with five rounded furrows, marked in the middle with a capillary ſtreak, approximating pale; on the other ſide flat: the interſtices between the grooves deepiſh, narrow, aſh-coloured.

S. Siſarum (n. 7.) has an elliptic fruit, with the ſtyliferous tubercle, but no veſtige of the calyx. Seeds five-cornered, acuminate at both ends, commonly curved in when ripe: ribs five, very narrow, linear, diſtant, ſtraw-coloured or yellowiſh; the interſtices between them wide, flattiſh, ferruginous or brown[g].

S. Falcaria is a native of many parts of Europe; alſo of Aſia and Africa.—Cultivated by Mr. Miller in 1759. It flowers in july and auguſt[h].

11. 12. 13. Natives of the Cape of Good Hope, where they were found by Thunberg[i].

14. Flowers yellow. Native of Greece. Loureiro has a ſpecies under this name, but that is more probably the ſame with *S. decumbens* of Thunberg, for *S. græcum* of Tournefort and Linneus has an erect jointed ſtem, and yellow flowers, whereas Loureiro deſcribes his plant as having the branches procumbent and ſometimes even creeping, and the flowers white, without any general involucre, and the partial only one-leafed[k].

15. Stem decumbent, dwarfiſh. Leaves radical, on long petioles, ſmooth, bipinnate: leaflets trifid. Umbel terminating, almoſt ſimple. Seeds ovate, obtuſe with the ſtyles permanent, ſtriated, ſmooth.

Native of Japan, on the iſland of Nipon, near Jedu and Fakona[l].]

16. Lower leaves pretty broad, and of a lucid green. Stem two feet high, terminated, in july, by an umbel of yellow flowers.

[It is a very ſmooth plant, with an upright ſtem, branched at the baſe and ſlightly ſtriated. Umbel flat, with unequal rays. Involucrets many-leaved, with linear-filiform acute leaflets. Seed elongated, ſmooth, ſtriated, ſemicylindrical[m].

Native of Sicily and the hills near Algiers. Cultivated by Mr. Miller.

17. 18. 19. Natives of the Cape of Good Hope, where they were found by Thunberg[n].

PROPAGATION AND CULTURE.

2—6. Being marſh or water plants, if cultivated in gardens, muſt be placed in tubs filled with water, having earth in the bottom, or by the ſides of canals or ponds.]

7. This plant is cultivated two ways, firſt by ſeeds, and afterward by ſlips from the root: the former method I think the more eligible, becauſe the roots which are raiſed from ſeeds, generally grow larger than thoſe raiſed by ſlips, and are leſs ſubject to be ſticky. The ſeeds ſhould be ſown the latter end of march or the beginning of april, either in broad caſt or in drills; the ground ſhould be light and moiſt, for in dry land the roots are generally ſmall, unleſs the ſeaſon proves very moiſt. If the ſeeds are good, the plants will appear in five or ſix weeks after they are ſown, and, when they have put out their leaves ſo as to be well diſtinguiſhed from the weeds, the ground ſhould be hoed over to deſtroy the weeds in the ſame manner as is practiſed for Carrots; and where the ſeeds are ſown in broad caſt, the plants ſhould be cut up, leaving them at the ſame diſtance as Carrots. Thoſe ſown in the drills ſhould be alſo thinned to the diſtance of four inches, and the ground hoed over to deſtroy the weeds. This ſhould be repeated three times, as is uſually done for Carrots, and if well performed in dry weather, will keep the ground ſufficiently clean unleſs much rain ſhould fall about midſummer, for the leaves will ſpread and cover the ground. In autumn, when the leaves begin to decay, the roots will be fit for uſe, and will continue till they begin to ſhoot in the ſpring, when they will become ſticky, as do thoſe which run up to ſeed the firſt ſummer.

To propagate this plant by offſets, dig up the old roots in the ſpring, before they begin to ſhoot, and ſlip off the ſide ſhoots, preſerving an eye or bud to each: plant them in rows one foot aſunder and four inches diſtant in the rows.

10. The leaſt part of the roots will grow, ſo that it will ſoon multiply of itſelf.

16. Sow the ſeeds ſoon after they are ripe.

DESCRIPTION, *&c.*

Stem ſhrubby, erect, ſmooth. Branches alternate, four-cornered. Leaves at the ends of the branches, alternate, frequent, oblong, waved, entire, obſcurely crenate towards the top, erect, the margin bent back, a finger's length, above green and wrinkled, beneath pale and dotted, evergreen with an aromatic taſte. Petioles ſemicylindrical, thickiſh, ſhort. Flowers terminating, in panicles. Peduncles round, thickening, ſhort.

Native of Japan, near Nagaſaki and elſewhere. The fruit is ripe in december[o].

Leaves roundiſh-ovate quite entire, capſules ovate briſtly opening from the top.

DESCRIPTIONS, *&c.*

1. The trunk of this tree riſes to forty or fifty feet, and is two feet in diameter. The leaves are large like thoſe of the Cheſtnut. The flowers alſo are very large, indented at the edge, oval and ending in a point, on a long pedicel, having two ſtipules deeply toothed, at the baſe. They grow in bunches from the axils [q].

Native of South America:] according to Mr. Miller, of South Carolina, whence he ſays the fruit with the outer covers were ſent to John Duke of Bedford, they were round and as large as a tennis-ball, armed all over with ſtrong ſpines, and divided regularly into four cells, each containing one ſmall Cheſtnut. He thinks that Plumier muſt have found this tree in Louiſiana, the heat of the Weſt India iſlands being too great for it. [If the Sloanea dentata be the ſame with the Caſtanea Sloanea of Miller, he cultivated it in 1756. Aublet ſays, that in Guiana it flowers in november.

2. This is a tall tree, with alternate leaves more than a foot long, angular-toothed, nerved, ſmooth on both ſides, ſomewhat coriaceous, on long round pubeſcent petioles. Flowers in axillary racemes towards the end of the branchlets, much ſhorter than the leaves, many-flowered, nodding, on long peduncles moſtly two together, bearing each one biggiſh green flower.—It differs from the preceding in having the leaves rounded at the end; the ſtipules linear, not cordate-deltoid; the flowers ſmaller with the calyx commonly five-leaved; and the capſules with longer briſtles.

Native of the Weſt Indies. Found in the iſland of St. Chriſtopher by Maſſon.

3. Height forty or fifty feet, with a cloven ferruginous or cinereous bark. Leaves alternate, about a foot long, ſlightly waved at the edge, nerved and veined, ſmooth on both ſides, coriaceous, on petioles almoſt the length of the leaves, round, ſpreading, even, thickened at the baſe and under the leaf. Stipules long, acuminate, deciduous. Racemes axillary, ſhorter than the petioles, many-flowered. Flowers ſmall, on ſhort one-flowered peduncles, with a ſingle little bracte at the baſe. Capſule the ſize of a large Walnut, four or five-celled and valved, the valves red within. Seeds ſolitary, covered with a red pulpy aril.

Native of South America and the Weſt Indian iſlands. Found in Guiana by Aublet, and in the iſland of St. Chriſtopher's by Maſſon [r].

DESCRIPTIONS, *&c.*

1. Roots perennial, compoſed of many thick fleſhy fibres, ſpreading wide, and ſtriking deep. Stems ſeveral, ſlender, angular, armed with ſhort crooked ſpines, and having claſpers on their ſides, by which they faſten themſelves to any neighbouring plant for ſupport, and riſe five or ſix feet high. Leaves ſtiff, heart-ſhaped, and acute-pointed, three-quarters of an inch broad at the baſe and about two inches long, of a dark green, marked with five longitudinal nerves, and the edges ſet with a few ſhort reddiſh ſpines. Flowers axillary in ſhort bunches, ſmall and whitiſh. Thoſe on the female plants are ſucceeded by red berries which ripen in autumn. [The berries are ſometimes black; and there is a variety which has the leaves eared at the baſe.

Native of the South of France, Italy, Spain, Carniola; near Tripoli, and between Rama and Joppa.—Cultivated in 1656, by Mr. John Tradeſcant, junior. It flowers in ſeptember[s].

The druggiſts in the South of Europe often ſell the roots of this ſpecies for thoſe of Sarſaparilla. (n. 4.) They have the ſame qualities, but in an inferior degree; and may be diſtinguiſhed by being larger, more porous, much leſs compreſſed, not ſo well packed, and faſtened by thread or oziers[t].]

2. Roots like thoſe of the preceding. Stems four-cornered and prickly, mounting to the tops of trees by their claſpers. Leaves two inches long, and an inch and three quarters broad at the baſe, having five longitudinal nerves, but no ſpines on their edges. The flowers and fruit are like thoſe of the firſt ſort. Native of Syria.

[3. Petioles two-toothed, not cirrhoſe. Claſpers from the axils or rudiment of the peduncle.——

[s] Hort. kew. [t] Villars.

Digitized by Google

Native of Ceylon [s]. Introduced in 1778, by Patrick Ruſſel, M. D. [x]

Loureiro has a ſpecies, under the name of Smilax perfoliata, which, as he ſays, ſeems to be allied to Rumphius's plant, which Linneus makes to be ſynonymous with his Sm. zeylanica: it differs however from that in having perfoliate ſtipules and five-nerved leaves. It is found on the woody hills of Cochinchina.

Desfontaines has a ſpecies, under the name of S. mauritanica, which is not the ſame with the excelſa, as appears from comparing the plant with the ſpecimens of that in Tournefort's and Vaillant's herbariums. The ſtem is prickly, angular and ſcandent; the leaves cordate, mucronate, unarmed or very ſeldom prickly, marked with about ſeven nerves, and the berries are red. It is allied to S. aſpera, but the ſtem is higher, the leaves three or four times as large and not ſpotted. They vary, ſome being prickly, others not, ſome are rounded at the end, but moſt are acute and mucronate.

Native of Algiers near Bone, and of mount Atlas.

4. Root perennial, divided into ſeveral branches, which are ſomewhat thicker than a gooſe quill, ſtraight, externally brown, internally white, and three or four feet in length. Stems ſhrubby, long, ſlender, ſcandent. Leaves alternate, pointed, with long tendrils at the baſe. Flowers lateral, uſually three or four together upon a common peduncle [y].

Native of America (Peru, Braſil, Mexico, Virginia.) Cultivated in 1691, by Mr. Foſter, according to Plukenet. It flowers in july and auguſt [z]. The root, as a medicine, was introduced into Spain, according to Caſpar Bauhin, about the year 1573, but Monarda informs us, that it was brought from New Spain to Madrid twenty or thirty years before that. The common name is of Spaniſh origin, from Zarza red, and Parilla a little vine.

Sarſaparilla, at its firſt introduction, was conſidered as an undoubted ſpecific in ſiphilitic and ſome chronic diſorders; but whether owing to a difference of climate or other cauſes, European practitioners ſoon found that it by no means anſwered the character which it had acquired in the Spaniſh Weſt Indies, and therefore it became very much neglected. Many phyſicians however ſtill conſider it as a medicine of much efficacy, and aſſert that the lues venerea is much ſooner ſubdued, by giving Sarſaparilla along with Mercury. It is in frequent uſe at moſt of the London hoſpitals; and Dr. Woodville relates, that he has known patients, after the uſe of Mercury, much ſooner reſtored to health by this root, than could have been accompliſhed by any other medicine with which we are acquainted, eſpecially when employed in powder.

This root is alſo recommended in rheumatic affections, ſcrophula, and cutaneous complaints where an acrimony of the fluids prevail. It may be given in decoction or powder, and ſhould be continued in large doſes for a conſiderable time [a].

5. Native of the Weſt Indies, in the Caribbee iſlands, St. Vincent. Stem fruteſcent, ſcandent. Branches ſubdivided, diverging, round, rigid, prickly, with raiſed decurrent lines between the prickles, which are ſtout, remote, thicker at the baſe, ſtretched out. Leaves alternate, veined, quite entire, rigid, on ſhort petioles ſheathing at the baſe and keeled. Flowers in peduncled umbels many together. Peduncles ſhorter than the petioles: pedicels the length of the peduncles, one-flowered. Flowers ſmall, greeniſh. Berry roundiſh, the ſize of a black Currant, blackiſh blue [b].]

6. Stems taper, very ſtrong, armed with ſhort ſtiff ſpines, and riſing twenty feet high by their claſpers. Leaves thick, four inches long, and three inches and a half broad at their baſe, ending in an obtuſe point, and having five longitudinal veins. Flowers in cloſe bunches. Berries red.

[Stem round, branched, with claſpers in pairs, and a few very ſhort ſcattered prickles. Leaves acute, three-nerved, ſmooth, alternate, ſeldom cordate or retuſe; without any ſtipules. Flowers in ſmall axillary umbels. Berry ſmall, round, red, one-ſeeded. Root horizontal, creeping far and wide, with oblong tubers, knobbed and warted, ſometimes branched, pale or reddiſh within, half a foot long, roundiſh, ſcattered [c]. According to Rochon, the root is as large as a child's hand, twiſted, full of knots, reddiſh on the outſide, fleſh-coloured in the heart, and deſtitute of ſmell. It muſt be choſen full, heavy and compact, of a reddiſh colour, and free from rottenneſs; for it is much ſubject to be gnawed by worms. It is employed with ſucceſs as a medicine in the province of Quanſi in China, where it abounds. The Chineſe uſe it for food, inſtead of Rice; and this contributes not a little to render them luſty [d].

Native of China, Cochinchina and Japan] Mr. Miller, who cultivated it in 1759, ſays, that he had it from Carthagena in New Spain; and that it was the ſame which he received from China by the title of China-root.

[Browne ſays, it is frequent in the more cool inland parts of Jamaica, where it riſes from a thick porous root, and climbs by a pretty ſlender rigid ſtem to the top of the talleſt trees in the woods; that it has a few prickles towards the bottom, divides into many branches at the top, and throws out its winding tendrils from the foot-ſtalks of the leaves; that the root is commonly uſed in Jamaica, and obſerved to anſwer as well as that from the Eaſt Indies; that it is of a ſheathing nature, and a very fit ingredient in all diluting apozems; that the plant might eaſily be propagated ſo as to ſupply the European markets, but what grows wild is more than ſufficient to ſupply the inhabitants, and ſerves frequently to feed the hogs, which are ſaid to live chiefly upon it, when there is a ſcarcity of wild fruit.

7. Stem naked, flexuoſe, with a very few ſtraight prickles. Leaves naked, five-nerved, wider than long, acute, on ſhort petioles, with two filiform claſpers.

Native of Canada, where it was found by Kalm [e]. Cultivated before 1760, by Archibald Duke of Argyle [f].]

8. Stalk thick, taper, riſing by claſpers ten or twelve feet high. Leaves thick, three inches and a half long, and an inch and half broad. Flowers axillary in round bunches, and ſucceeded by black berries.

[Linneus remarks, that the leaves, as to their conſiſtence, are the thickeſt of any in the genus.

Native of Virginia and Carolina. Cultivated by Mr. Miller in 1739. It flowers in july [g].]

9. Stems taper. Leaves four inches long, and two inches and a half broad at their baſe, having ſeven longitudinal veins: the flowers come out in long looſe bunches from the ſide of the ſtalks, and the berries are black.

[Native of North America. Cultivated in 1739, by Mr. Miller. It flowers in june and july [h].

10. Stem naked, flexuoſe, with a few ſtraight prickles black at the tip. Leaves annual, acute, on ſhort petioles, from which ſpring two capillary claſpers. Umbels of flowers below the leaves, on peduncles which are ſcarcely longer than the petiole.

Native of Canada [i]. Introduced in 1775, by Mr. William Young [k].]

Mr. Miller has a ſpecies under the ſame name, but without any reference to Linneus. He ſays that it grows naturally at Carthagena in New Spain; that it has ſtrong taper ſtalks armed with a few ſhort ſpines; that the leaves are thick, unarmed and heart-ſhaped, five inches long, and three inches and a half broad at their baſe, ending with an acute point; and that it climbs to the height of thirty feet.

[Loureiro has alſo a S. caduca, and refers to Linneus, and alſo to Tournefort, inſt. 694. n. 3.—The ſtem is very prickly at the baſe, and the claſpers are in pairs from the petioles. Leaves all broad-ovate, re-

tuſe,

Digitized by Google

S M I

tuſe, ſmooth, alternate, Stipules none. Flowers in ſmall lateral umbels.

Native of the woods of Cochinchina.—It is not probable that the ſame ſpecies is indigenous of three climates ſo different as that, the Spaniſh Weſt Indies and Canada.

11. Native of North America. Introduced about 1778, by Mr. William Young. It flowers in june and july [l].

12. Native of North America. Cultivated in 1669, by the Dutcheſs of Beaufort. It flowers in july [m].

The leaves have the form of the hederaceous plants, but not the conſiſtence, for they are thin. The little umbels of ſmall flowers are on very long ſlender peduncles, from the boſoms of the leaves. It was brought to England by Vernon and Kreig, at their return from Maryland [n].

Plukenet's figures 3 and 4 are wrong marked, and ſhould be tranſpoſed to agree with the names under the plate; the figure at top marked 4 is Phytolacea decandra.

13. Stem four-cornered, altogether flexuoſe. Petioles the length of the earlets or lobes of the heart of the leaf. Leaves narrower than in moſt of the ſpecies [o].

14. Stem herbaceous, unarmed, round, ſhort, very branching, ſcandent, cirrhoſe. Leaves quite entire, ſmooth, three-nerved, alternate. Root filiform, long, not tuberous [p].

Supported on trees and ſhrubs, claſping them with their tendrils. Leaves long, and narrowed at both ends, thick, ſtiff and ſhining, with a ſingle rib in the middle, alternate at wide diſtances. At the ends of the ſmaller branches are produced greeniſh-white flowers in tufts, ſucceeded by globular mucilaginous red berries, each containing a very hard round ſtone. Theſe ſerve as food to birds [q].

Native of Virginia, Carolina and Cochinchina.—Introduced in 1785, by Mr. William Young [r].

15. Stem ſhrubby, very long, ſlender, with few ſcandent branches. Leaves ſmall, the lower cordate, the upper ovate-lanceolate, three-nerved, quite entire, flat, with the margin bent back. Flowers in lateral umbels. Berries red. The root is horizontal, ſimple, thick, ſhort, tubercled, with many, long, undivided fibres [s]. According to Browne, the roots are ſmall, and divided into a number of ſlender branches. He thinks it to be very like the Sarſaparilla of Piſo, p. 278. Thunberg remarks, that there are two, three, four, or five ſeeds in a berry.

Native of Virginia, Jamaica, China and Cochinchina.—In the latter they uſe the ſtem for making baſkets and other wicker ware [t].

In Chineſe it is named Cum Kong Cunn, and is frequently uſed by them inſtead of the true China root. A ſmall quantity of it even in cold water tinges of a deep red; whereas the true root yields a light yellow brown [u].

16. Forſter, in his genera, made this a new genus, under the name of *Ripogonum*, from ῥιψ, ῥιπος, *vimen*, and γονυ, *genu*, *a joint*; being a vimineous, jointed plant, as indeed moſt of the Smilaces are, to which genus he afterwards referred it. The leaflets of the calyx are lanceolate, acute and almoſt erect; the anthers are linear, quadrangular, three times as long as the calyx, erect; the germ globular; the ſtyle filiform of the ſame length with the calyx, and the ſtigma blunt; the berry globular and two-ſeeded; the ſeeds ſolitary and hemiſpherical.—Native of New Zealand.

17. Native of New Caledonia [x].

In the appendix to the Journal of a voyage to New South Wales by John White, Eſq. Surgeon General to the ſettlement, a ſhrub is figured under the name of the Tea tree of New South Wales, Sweet Tea Plant, or Smilax glycyphylla. The leaves are about two inches long, ovate-lanceolate, pointed, entire, marked with three longitudinal ribs, and many tranſverſe elevated veins, ſmooth and ſhining above, glaucous beneath, with a thick cartilaginous edge. They have the taſte of liquorice root accompanied with bitter, and the infuſion is ſaid to be good for the ſcurvy, and not unpleaſant. It is judged to belong to this genus, but the leaves only having been ſeen, the generic and even the ſpecific character cannot be aſcertained.]

18. The 18th ſort grows naturally at La Vera Cruz in New Spain; this has a thick, taper, prickly ſtalk, which climbs up the neighbouring trees to the height of thirty or forty feet. The leaves are thick, ſtiff, and unarmed; they are ſeven inches long, and have two round ears at their baſe, where they are three inches and a half broad, but the other part of the leaves are two inches broad at their top, where they are rounded; they have three longitudinal veins, and ſtand on ſhort foot-ſtalks.

19. The 19th ſort grows alſo naturally at La Vera Cruz; this has ſlender, taper, prickly ſtalks, which faſten themſelves to any neighbouring ſupport by their claſpers, and riſe eight or ten feet high. The leaves are four inches and a half long, and two and a half broad in the middle; they have no ſpines on their edges, but their midrib and veins on their under ſide are armed with ſhort reddiſh ſpines.

20. The 20th ſort grows naturally in Jamaica. The ſtalks of this are ſlender, angular, and prickly; the leaves are ſpear-ſhaped, ending in acute points; they are three inches long, and half an inch broad, having no ſpines; their baſe is a little rounded, but they have no ears.

21. The 21ſt ſort grows naturally in Jamaica; this has thick, fleſhy, creeping roots. The ſtalks are taper and unarmed; theſe climb up the neighbouring trees and buſhes to the height of ten or twelve feet. The leaves are ovate and end in acute points; they are five inches long and three broad, and have three longitudinal veins, but no ſpines.

[Miller has the ſame ſynonym of Plukenet under his S. canellæfolia, which Linneus refers to his S. Pſeudo-China. See n. 15.]

22. The 22d ſort grows naturally in Carolina; this has taper unarmed ſtalks which riſe three or four feet high. The leaves are ovate-heart-ſhaped, about three inches long, and almoſt two broad, rounded at their points, and have three longitudinal veins. The flowers come out from the wings of the ſtalk at every joint, ſtanding upon ſhort foot-ſtalks, formed in a round bunch; theſe are ſucceeded by roundiſh red berries.

23. The 23d ſort grows naturally in Jamaica, and alſo in Maryland. The ſtalks of this are ligneous, taper, and unarmed; theſe have very long claſpers, by which they faſten to any neighbouring ſupport, and riſe twenty feet high. The leaves are ſome ovate and others heart-ſhaped; they are about three inches and a half long, and two and a half broad. The flowers come out from the wings of the ſtalk in oblong bunches; theſe are ſucceeded by red berries.

[Miller, under his hederæfolia, has given Linneus's character of S. Pſeudo-China, with a reference to Plukenet's figure, which Linneus attributes to his S. herbacea, n. 12.]

PROPAGATION AND CULTURE.

Theſe plants are many of them preſerved in the gardens of the curious for the ſake of variety, but ſome of them may ſo be diſpoſed as to make them ornamental, becauſe thoſe ſorts which grow naturally in North America, and the two firſt ſorts, are ſo hardy as to thrive in the open air in England; and as they retain their verdure all the year, if the plants are placed on the borders of woods or groves in gardens, and their branches properly ſupported, they will ſcreen the nakedneſs of the ground under the trees from ſight, and in winter, when their leaves are in beauty, they will make a pleaſing variety, when the plants are properly intermixed with other evergreens; and as ſome of the ſorts will riſe five or ſix feet high, they will ſhut out from view any diſagreeable objects.

Thoſe ſorts which require a ſtove to protect them in winter are little eſteemed, becauſe they require much room; and as their flowers have no beauty to recommend them, few perſons care to be at the trouble of preſerving them for that of their leaves, becauſe there are

[l] Hort. kew. [m] Idem. [n] Ray. [o] Linn. ſuppl. [p] Loureiro. [q] Cateſby. [r] Hort. kew. [s] Loureiro. [t] Idem. [u] Blake, MS. [x] Forſter.

are many other plants whoſe leaves make a better appearance, and the plants do not require ſo much room, ſo theſe plants are rather the proper furniture of botanic gardens than thoſe of pleaſure.

They are all propagated by ſeeds, which muſt be procured from the countries where they naturally grow, for there are none of theſe plants which produce ripe ſeeds here. Thoſe ſorts which have been brought from the north of America, ſometimes produce flowers in England, but the ſummers here are neither warm enough, nor of a proper duration to ripen their ſeeds, ſo that theſe are propagated by parting their roots; for when the roots have obtained ſtrength, they ſpread very far in the ground, and ſend up ſtalks at a diſtance from the old roots, whereby they may be greatly increaſed when the ſorts are once obtained. The beſt time for tranſplanting and parting their roots is early in autumn, that the offſets or young plants may have time to get good roots before the froſt comes on, and if after they are planted, the cold ſhould come on earlier, or be more ſevere than ordinary, if the ſurface of the ground about their roots is covered with ſome old tanners bark or mulch to keep the froſt out of the ground, it will preſerve them; but theſe roots ſhould not be parted oftener than every third or fourth year, for unleſs the roots are large, there will be few ſtalks to each, and they will make but little appearance.

The tender ſorts muſt be kept in pots, and plunged into the tan-bed of the bark-ſtove, in order to have them ſtrong; for although they will live in moderate warmth in winter, they will make but little progreſs, and their ſtalks will be ſhort, their leaves ſmall, and the plants weak, ſo will make but a poor appearance; therefore, unleſs they can be allowed room in the warm ſtove, and conſtantly kept in the tan-bed, they will not be worth preſerving.

All the ſorts grow naturally under hedges and in woods, therefore they ſhould be diſpoſed in ſuch a manner, as to imitate their places of growth, and not place them in the open ſun, where they will not thrive; therefore the hardy kinds ſhould be placed under the ſhade of trees, and the tender ones may be placed between the pots which contain tall plants, whoſe branches may ſcreen them from the ſun. Such of theſe plants as are tender muſt be frequently watered in hot weather, and ſhould then have a large ſhare of air admitted to them, but in winter they muſt be watered ſparingly, for their roots are apt to rot with too much wet.

When the ſeeds of theſe plants are obtained from abroad, they ſhould be ſown in pots filled with freſh light earth, and plunged into a moderate hot-bed, obſerving to water the earth frequently to keep it moiſt, becauſe the ſeeds, being hard, will not vegetate without a conſiderable ſhare of moiſture; theſe generally remain in the ground a whole year before they grow, ſo that if the plants do not come up the firſt ſeaſon, the pots ſhould be kept clean from weeds all the ſummer, and in winter the hardy ſorts ſhould be ſheltered from froſt under a common frame, and the tender ones plunged into the bark-bed in the ſtove: the following ſpring they muſt be again plunged into the hot-bed, which will bring the plants up very ſoon. When the plants are come up, they muſt be conſtantly kept clear from weeds, and frequently watered in warm weather, and toward the end of may the hardy ſorts ſhould be inured to the open air by degrees, and in june they may be removed out of the bed, and placed abroad in a ſheltered ſituation, where they ſhould remain till the froſt comes on in autumn, when they muſt be removed into ſhelter. If the pots are plunged into an old tan-bed under a frame, where they may be protected from the froſt, and in mild weather be expoſed to the open air, they will thrive much better than with more tender treatment.

The tender ſorts ſhould be plunged between the other pots in the bark-bed of the ſtove, where they ſhould remain all the winter. Theſe plants ſhould remain untranſplanted in the ſeed-pots till the following ſpring, when they ſhould be turned out of the pots, carefully ſeparated, and planted into pots filled with freſh earth; and if the hardy ſorts are plunged into a very temperate hot-bed, it will cauſe them to take new root very ſoon, and greatly ſtrengthen the plants; but the tender ſorts ſhould be plunged into a good hot-bed of tanners-bark to bring the plants forward, that they may get ſtrength before winter, when they muſt be treated in the manner before directed.

The hardy ſorts ſhould be kept in pots for two or three years that they may be ſheltered in winter, by which time they will have ſtrength enough to bear the cold in the open air; ſo in the ſpring they may be turned out of the pots, and planted where they are deſigned to remain, obſerving, if the ſpring ſhould prove dry, to refreſh them now and then with water, as alſo to lay ſome mulch about them to prevent the earth from drying; and while the plants are young, if ſome mulch is laid about their roots in winter, it will be a ſure method to preſerve them.

SMITHIA. (*So named in honour of James Edward Smith, M.D. F.R.S. &c. Preſident of the Linnean Society, Poſſeſſor of the Linnean collection, author of ſeveral uſeful and ſplendid works.*)

Lin. gen. Schreb. n. 1760. *p.* 809. *Ait. kew.* 3. 512.

Claſſ. 17. 4. Diadelphia Decandria.

Nat. order of *Papilionaceæ* or *Leguminoſæ*.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, two-lipped: *ſegments* ovate-lanceolate, almoſt equal.

COR. papilionaceous. *Standard* obcordate. *Wings* oblong, obtuſe, a little ſhorter than the ſtandard. *Keel* linear-oblong, cloven at the baſe, length of the wings.

STAM. *Filaments* ten, united into two equal bodies. *Anthers* oblong.

PIST. *Germ* contracted at the baſe of the calyx. *Style* capillary, permanent. *Stigma* ſimple.

PER. *Legume* incloſed within the calyx, compoſed of from four to ſeven joints; diſtinct, connected by the permanent ſtyle, orbicular, muricated, one-ſeeded.

SEEDS kidney-form, compreſſed, ſmooth.

ESSENTIAL CHARACTER.

Legume with diſtinct one-ſeeded joints, connected by the ſtyle. *Stam.* divided into two equal bodies.

SPECIES.

1. Smithia ſenſitiva. *Annual Smithia.*

Ait. kew. 3. 496.

DESCRIPTION, *&c.*

Root annual. Stem decumbent, round, even. Branches ſpreading very much. Leaves alternate, abruptly pinnate, compoſed of from four to ten obovate-oblong leaflets, briſtly on the edge and along the rib beneath. Petiole very ſhort; rachis briſtly. Stipules in pairs, permanent, ſemi-lanceolate above the inſertion, quite entire, acuminate; below the inſertion bifid: one ſegment blunt, the other longer, acuminate. Racemes axillary, from three to ſix-flowered. Peduncle longer than the petiole, filiform. Pedicels ſhorter than the calyx. Bracte under each of the pedicels, like the ſtipules, but leſs produced downwards: bractes under the calyx two, reſembling the exterior calyx, ovate-lanceolate, muricate. Calyx muricate with briſtle-bearing tubercles. Corolla yellow.

Native of the Eaſt Indies, and introduced in 1785, by John Gerard Koenig, M.D. It flowers in october[y].

SMYRNIUM. (Σμυρνιον *of Dioſcorides, from the city of Smyrna:* or, *from* σμυρνα *the ſame with* μυρρα, *the root yielding a gum like Myrrh.*)

DESCRIPTIONS, *&c.*

1. The lower leaves are ſuperdecompounded, and the leaflets are in threes, ovate and indented. Stem ſmooth, hollow, three feet high, dividing towards the top into two or three branches. At each joint is placed one large orbicular leaf, the baſe of which is embracing; theſe are of a yellow colour, and their edges are entire. The branches are terminated by

ſmall umbels of yellowiſh flowers, on pedicels of unequal lengths.

Mr. Miller names this S. rotundifolium, and diſtinguiſhes the long-leaved variety under the name of S. perfoliatum.—The lower leaves of this, he ſays, are larger, the ſtalk is not ſo high, the ſtem-leaves are much larger, cordate-ovate and indented, and their texture is thinner. The umbels and ſeeds are ſmaller. He affirms that he has cultivated both many years, and has not found either of them alter: [And yet, ſays Parkinſon, both ſorts have riſen in my garden from one kind of ſeed, and therefore I hold them to be one.

Native of Candia and Italy. Ray found it in Sicily, near Punto Cerciolo, not far from Puzzallu.—It groweth, ſays Gerarde, in my garden (1596) in great plenty.—It is a biennial plant, and flowers in may. The leaves are not properly perfoliate, but embracing.

2. Native of Egypt.

3. Native of the Cape of Good Hope.

4. Root biennial, fleſhy, branched. The whole herb of a pale bright green, (often, ſays Withering, of a ſickly yellowiſh caſt,) ſmooth, ſucculent, in flavour ſomething like Celeri, but more ſtrong and bitter. Stem round, ſtrong, deeply grooved. Upper leaves ternate, lower triternate; leaflets wide, varying in form, gaſhed and ſerrate, ſubpetioled. Common petiole dilated at the baſe, ventricoſe and nerved. Umbels terminating, globular, many-rayed. Flowers ſmall, numerous, irregular, greeniſh yellow[a]. Fruit large, black, remarkably gibbous, deeply grooved: each ſeed ſemilunate, thick, with three acute-angled and almoſt winged ribs on the back, and ſomewhat wrinkled between the ribs; the belly prominent with a longitudinal groove in the middle[a].

Native of France, Spain, Italy, Belgium, and Britain. It is rather a maritime plant, and is found near our coaſt in many places; as about Scarborough caſtle, and about Dover, common. Ray ſays it is common in Angleſea; and Pennant, that it almoſt covers the S. W. end of the iſland, where it is greedily eaten when boiled, by ſailors returning from long voyages. It is very common in all the weſtern counties, and in the flat parts of Glouceſterſhire. About Poole, on the ramparts going into Wareham, and in many other places in Dorſetſhire. It occurs alſo about many inland towns, as Nottingham, York, Bury, Newmarket, and about Mackerell's tower, Norwich; Bungay in Suffolk, ſeveral places in Cambridgeſhire, near Benſington, in Oxfordſhire, between Great Comberton and Wollerſhill, at Hill Croome and Pirton in Worceſterſhire. In the neighbourhood of London, about Deptford, Vauxhall and Batterſea. Cliffe in Kent. Cowley in Middleſex. In Scotland, upon the coaſt at Dunglaſs, on the edge of Berwickſhire.

It was noticed as indigenous of England by Turner. Parkinſon ſays it was firſt found wild in ſome of the Iſles about our own land by Mr. William Quicke, a worthy apothecary in his time, who gave him and Mr. William Cois a famous gentleman, and a great lover of plants, ſome of the ſeeds.

This plant was formerly eaten in various parts of Europe, either as a ſalad or pot-herb, whence, and from its blackneſs, the name *oluſatrum*. Ray ſays it was called *Alexanders*, becauſe in Italy and Germany it had long been denominated *herba alexandrina*; having been ſuppoſed to be brought from Alexandria. It flowers in may; and by the middle of july the ſtalks are dried up, but remain laden with large black ſeeds[b].]

5. The lower leaves of this are ſmaller than thoſe of the preceding, and more like thoſe of Smallage. The ſtalk riſes higher, and grows more erect. The lower ſtem-leaves are large and ſerrate; they ſtand by threes at the joints; their baſe ſet cloſe, having no foot-ſtalks: the upper leaves are of the ſame form, but ſtand by pairs. The umbels are much ſmaller, and the ſeeds are leſs.—Native of Crete or Candia.

6. Root perennial, black, and thick with cluſtered fibres. Stems ſeveral, ſtriated, angular, a palm and

[a] Smith. [a] Gærtner. [b] Engl. bot.

half

Digitized by Google

half in height, from the bottom of which ariſe petioles, membranaceous at the baſe, and then triangular, ſubdivided into three petioles, the middle one bearing five toothletted leaflets, and the other two, three only. Some of the ſtems emit branchlets from the axils of the leaves. Each ſtem and branch is terminated by an umbel of very ſmall yellow flowers. Seeds brown, ſtriated, not unlike thoſe of Caraway. The whole plant is acrid, bitter and aromatic [c].

Native of North America. (Dodart ſays, it was ſent by Richer, who was commiſſioned by the King of France to Acadia and Cayenne.) It was cultivated here before 1699, by Mr. Jacob Bobart [d]; to whom it was ſent by Sherard from the Paris garden. He deſcribes it as not more than eighteen inches or two feet in height; the leaves very like thoſe of Podagraria, divided by threes, acute, equally and not deeply ſerrate. Umbels flat, of golden or yellow flowers. Seeds ſmall, oblong, ſtriated, approaching very near to thoſe of Podagraria [a].

7. Root perennial. Stem a foot and half high, even, little branched. Leaves almoſt like thoſe of Aquilegia or Columbine, triternate, oblong-ovate, ſmooth, quite entire, glaucous-green. Florets in the diſk of the umbellets male.

Native of Virginia [f]. Mr. Miller has this ſpecies, but without any deſcription.

PROPAGATION AND CULTURE.

Theſe plants are moſt of them biennial, periſhing after their ſeeds are ripe; they flower in june, and their ſeeds ripen in auguſt.

The fourth is that which was ordered for medicinal uſe, but is ſeldom now preſcribed; and at preſent is ſeldom cultivated in gardens, though formerly it was greatly uſed in the kitchen, before Celery was ſo much cultivated, which has taken place of Alexanders, and entirely ſupplanted it. The other ſorts are preſerved in botanic gardens for variety, but may be cultivated for the uſe of the kitchen. The firſt ſort is much preferable to the fourth for blanching, and will be tenderer, and not quite ſo ſtrong.

All theſe plants may be propagated by ſowing their ſeeds upon an open ſpot of ground in auguſt, as ſoon as they are ripe; for if they are preſerved till ſpring, they often miſcarry; or at leaſt do not come up until the ſecond year; whereas thoſe ſown in autumn rarely fail of coming up in the ſpring, and will make much ſtronger plants than the other.

The common ſort, when cultivated for the table, ſhould be treated in the following manner:

In the ſpring the plants ſhould be hoed out, ſo as to leave them ten inches or a foot apart each way; and during the following ſummer, they muſt be conſtantly cleared from weeds, which, if permitted to grow among them, will draw them up ſlender, and render them good for little. In february following the plants will ſhoot up again vigorouſly, at which time the earth muſt be drawn up to each plant, to blanch them, and in three weeks after they will be fit for uſe, when they may be dug up, and the white part preſerved, which may be ſtewed and eaten as Celery.

DESCRIPTION, &c.

This is a ſmall tree from twelve to twenty feet high, with a branching trunk, and a cloven aſh-coloured bark, green within. The wood is ſpongy. The branches are looſe, bent down, divaricating, very long. The leaves are in cluſters towards the ends of the branchlets, obovate-oblong, acute, quite entire, ſmooth, thickiſh and ſomewhat ſucculent, from three to ſeven inches in length, on round ſmooth petioles, five times ſhorter than the leaves. Flowers terminating, ſubſeſſile, ſubſolitary, very large. Peduncles very ſhort, thick, round, ſmooth, one-flowered. Calyx from two to three inches long, ſubquinquefid, as the fruit ripens burſting to the baſe into three or five ſegments. Tube of the corolla greeniſh white. Border ten times ſhorter than the tube, patulous, pale fleſh-colour, ſomewhat irregular, veined: the opening four inches in diameter; ſegments wide, very bluntly waved, crenulate at the edge, almoſt equal the upper ones being ſcarcely larger. Filaments inſerted into the baſe of the tube, yellow: anthers large, ferruginous. Germ ſmooth: ſtyle aſcending at the top and yellow: lobes of the ſtigma roundiſh, green. Berry often the ſize of a hen's egg, but thicker below, acuminate with the permanent baſe of the ſtyle, ſmooth and even, white, pulpy and red within. Seeds black. The very handſome ſweet flowers appear in the months of january and february. The fruit ripens in auguſt, and is of a ſweet ſubacid flavour.

Native of Jamaica, on very large trees, or in the fiſſures of rocks, ſcandent and ſubparaſitical. It is known there by the name of Peach-coloured Trumpet Flower [g].

Mr. Saliſbury deſcribes it as a ſhrub from nine to twenty feet in height. The root brown, running out far, very much branched, of a ſpongy woody ſubſtance. Stem aſh-coloured, ſcandent, round: branches many, bent variouſly, ſome of them very long: the ſtem is more or leſs rooting, cloven; at top pale green, pubeſcent and viſcid; the wood ſpongy. Leaves cloſe, alternate, frondoſe: petiolts purpliſh-green, re-

[g] Swartz.

curved

Digitized by Google

curved a little, ſemicylindric, pubeſcent, and viſcid, concave above with the middle line eminent: ſurface green above, paler beneath, much longer than the petioles, ſpreading very much and recurved, obovate-lanceolate, quite entire, acuminate, viſcid and pubeſcent on both ſides, a little ſhining, flattiſh, fleſhy: nerves ſeveral, the middle one thicker and uniting with the petiole: they are produced and fall every year. Flowers fragrant, nodding, ſolitary, or ſometimes but ſeldom two or three together. Peduncles pale green, terminating the branchlets; thick, four or five lines in length, obconical, jointed at the inſertion, very minutely viſcid-pubeſcent. Receptacle pale green, uniting with the peduncle, than which it is ſhorter and thicker, indiſtinctly angular, very minutely viſcid-pubeſcent. Calyx pale purpliſh green, inſerted into the margin of the receptacle, three inches long or more, erect, tubular, five-cornered with the ſide a little concave, in the time of flowering ſhortly and unequally cloven at two or three of the angles, afterwards as the fruit ſwells frequently more deeply to the very baſe: ſegments erect, half-lanceolate, quite entire, a little acuminate; minutely viſcid-pubeſcent eſpecially within; on the outſide ſomewhat ſhining: permanent. Corolla inſerted into the margin of the receptacle, ſeven or eight inches long: tube pale yellow green, a little ſhorter than the calyx, declining towards the lower ſide of it, ſcarcely three lines in diameter at bottom, widening gradually above, five-cornered, depreſſed a little on the outſide where the filaments are inſerted: limb or border for the moſt part whitiſh, much longer than the tube; funnel-form below, but quickly ſwelling out very much, ſo that the opening of the throat is about two inches in diameter; then being curved back, it is four inches and a half over at the upper opening, and is ſhortly five-cleft; the undivided part is indiſtinctly ten-cornered, five of the corners being continued from the lower ones of the tube and coloured on the inſide with a duſky-purple fillet, the remaining five ſpringing from the inſertion of the filaments, much more ſlender and having a very indiſtinct fillet or none at all: the ſegments are of a bright purpliſh colour on the outſide with the interſtices minutely ſuborbicular at the baſe, and very finely ciliate; the outmoſt ſemiorbicular, repand, flat; the three inner larger, widening on one ſide, gaſh-crenate and curled; the inner one very large, ſemiorbicular, the whole of it very elegantly curled and notchletted: it is ſmooth on the outſide at bottom and the reſt is even: it is coriaceous and deciduous. Filaments very pale yellowiſh green with a duſky purple baſe, inſerted into the mouth of the tube, decurrent, about half the length of the border, curved in, approximating, awl-ſhaped, ſmooth. Anthers very pale yellowiſh green with the ſides purple, inſerted at the baſe and there ſhortly cloven, erect, a little lunulate, four-cornered, with a ſhort dagger-point, two-celled; valves four, the two anterior ones a little narrower and ſtraighter; they open laterally, and after flowering become of a duſky purple, a little leſs, unequally ovate, very much compreſſed: the pollen is of a very pale yellow colour. Style purpliſh at the tip, round and ſmooth. Stigma pale green, compreſſed, pubeſcent, finely channelled. Fruit of a very pale yellowiſh green, ſuperior to the diſk of the receptacle, pyramidal, ſmooth and even, from an inch and half to two inches in length, ovate, four-celled almoſt to the top, and then two-celled, two of the partitions gradually failing; there are two central receptacles, on long ſtipes, deeply two-lobed, variouſly repand-ſinuous. The ſeeds are ſeſſile on all ſides about theſe, ferruginous, kidney-form, dicotyledonous [h].

The above may ſerve as an example of very minute and accurate deſcription.—This plant was introduced here by Mr. Maſſon in 1781, and flowers in march [i].

SOLANI FRUCTU. See *Rauwolfia.*

[h] Linn. tranſ. 6. [i] Hort. kew.

SOLANO CONGENER. See *Paris*, and *Trillium.*

SOLANOIDES. See *Rivina.*]

SOLANUM (*of Pliny, &c. Derivation uncertain. Some derive it from* Sol, *the ſun; others ſay it is q.* Sulanum, *from* Sus, *being ſuppoſed to be ſerviceable in diſorders of ſwine: both conjectures are improbable.*)

Lin. gen. n. 251. *Reich. n.* 268. *Schreb. n.* 337. *Tournef. t.* 62. *Juſſ.* 126. *Gærtn. t.* 131. Melongena. *Tournef. t.* 65. Lycoperſicon. *Tournef. t.* 63.

Claſſ. 5. 1. Pentandria Monogynia.

Nat. order of *Luridæ. Solaneæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, half-five-cleft, erect, acute, permanent.

COR. one-petalled, wheel-ſhaped: *tube* very ſhort: *border* large, half-five-cleft, from reflex flat, plaited.

STAM. *Filaments* five, awl-ſhaped, very ſmall. *Anthers* oblong, converging, ſubcoaleſcent, opening at the top by two pores.

PIST. *Germ* roundiſh. *Style* filiform, longer than the ſtamens. *Stigma* blunt.

PER. *Berry* roundiſh, ſmooth, dotted at the top, two-celled; with a convex fleſhy *receptacle* on each ſide.

SEEDS very many, roundiſh, neſtling.

ESSENTIAL CHARACTER.

Cor. wheel-ſhaped. *Anthers* ſubcoaleſcent, opening at top by a double pore. *Berry* two-celled.

SPECIES.

1. *Unarmed.*

[1. Solanum laurifolium. *Bay-leaved Nightſhade.*
Lin. ſyſt. 223. *Willd.* 1. 1025. *ſuppl.* 148.
Stem unarmed arboreous, leaves petioled ovate-oblong tomentoſe beneath, panicle terminating dichotomous divaricating.]

2. Solanum verbaſcifolium. *Mullein-leaved Nightſhade.*
Lin. ſpec. 263. *ſyſt.* 223. *Reich.* 1. 510. *Willd. phyt.* 1. *p.* 5. *n.* 17. *Jacqu. hort.* 1. *p.* 5. *t.* 13. *Pluk. phyt. t.* 316. *f.* 1. *Lour. cochinch.* 128. *ed. Willd.* 159.
S. bahamenſe. *Mill. dict. n.* 24.
S. arboreſcens verbaſci folio. *Plum. ſpec.* 4.
Stem unarmed ſhrubby, leaves ovate tomentoſe quite entire, corymbs bifid terminating.

[3. Solanum auriculatum. *Ear-leaved Nightſhade.*
Lin. ſpec. ed. Willd. 1. 1025. *Ait. kew.* 1. 246. *Vahl ſymb.* 3. 38. *L'Herit. ſolan. t.* 1.
S. mauritianum. *Scop. inſubr.* 3. 16. *t.* 8.
Stem unarmed ſhrubby, leaves ovate acuminate tomentoſe quite entire, ſtipules cordate, corymbs bifid terminating.

4. Solanum pubeſcens. *Pubeſcent Nightſhade.*
Lin. ſpec. ed. Willd. 1. 1026. *Willd. phytog.* 1. 5. *n.* 18. *t.* 3.
Stem unarmed tomentoſe ſhrubby, leaves ovate decreaſing at the baſe quite entire pubeſcent, racemes ſubumbelled axillary.

5. Solanum bombenſe. *Tierra Bomba Nightſhade.*
Lin. ſpec. ed. Willd. 1. 1026. *Jacqu. amer.* 49.
Stem unarmed fruteſcent, leaves oval attenuated to both ends quite entire, racemes cymed.]

6. Solanum Pſeudo-Capſicum. *Shrubby Nightſhade* or *Winter Cherry.*
Lin. ſpec. 263. *Reich.* 1. 510. *Willd.* 1. 1026. *hort. cliff.* 61. *upſ.* 48. *Kniph. cent.* 6. *n.* 87.
S. fruticoſum bacciferum. *Bauh. pin.* 166. *Raii hiſt.* 673.
S. frut. americanum dictum Amomum Plinii. *Park. theat.* 353. *f.* 1. *parad.* 431. *t.* 429. *f.* 7.
Amomum Plinii. *Ger.* 289. *emac.* 361.
Pſeudocapſicum. *Dod. pempt.* 718.
Stem unarmed ſhrubby, leaves lanceolate repand, umbels ſeſſile.

[7. Solanum microcarpum. *Small-fruited Nightſhade.*
Lin. ſpec. ed. Willd. 1. 1026. *Vahl ſymb.* 2. 40.
S. diphyllum. *Forſk. deſcr.* 63. *n.* 134.
Stem unarmed ſhrubby, leaves ovate-lanceolate, umbels lateral peduncled.

8. Solanum terminale. *End-flowering Nightſhade.*
Lin. ſpec. ed. Willd. 1. 1027. *Vahl ſymb.* 2. 40. *Forſk. deſcr.* 45.
Unarmed fruteſcent, leaves lanceolate-ovate moſtly quite entire hairy, umbels terminating.

9. Solanum

Digitized by Google

9. Solanum pauciflorum. *Few-flowered Nightſhade.*
Lin. ſpec. ed. Willd. 1. 1027. *Vahl ecl.* 1. 20.
Leaves ovate quite entire, branches and calyxes ten-toothed tomentoſe, peduncles axillary in pairs one-flowered.

10. Solanum diphyllum. *Two-leaved Nightſhade.*
Lin. ſpec. 264. *Reich.* 1. 511. *Willd.* 1. 1027. *vir. cliff.* 15. *hort. cliff.* 61. *Pluk. phyt. t.* 111. *f.* 4. *Jacqu. collect.* 2. 331. *ic. rar. t.* 322.
Stem unarmed ſhrubby, leaves in pairs, one ſmaller than the other, flowers in cymes.

11. Solanum fugax. *Fugacious Nightſhade.*
Lin. ſpec. ed. Willd. 1. 1027. *Jacqu. collect.* 4. 123. *ic. rar. t.* 324.
Stem unarmed ſhrubby dichotomous divaricating, leaves lanceolate quite entire ſmooth, peduncles ſolitary axillary one-flowered, calyx ten-toothed.

12. Solanum geminatum. *Two-flowered Nightſhade.*
Lin. ſpec. ed. Willd. 1. 1027. *Vahl ecl.* 1. 21.
Leaves ovate quite entire, calyxes ten-toothed ſmooth, peduncles axillary in pairs one-flowered, ſtem ſcandent.

13. Solanum retrofractum. *Broken Nightſhade.*
Lin. ſpec. ed. Willd. 1. 1028. *Vahl ecl.* 1. 21.
Leaves ovate ſmooth, branches axillary retrofracted, umbels axillary and terminating ſeſſile, calyxes truncate.

14. Solanum ſtellatum. *Starry Nightſhade.*
Lin. ſpec ed. Willd. 1. 1028. *Jacqu. collect.* 3. 254. *ic. rar. t.* 325.
Stem unarmed ſhrubby ſcandent flexuoſe, leaves ovate ſmooth acuminate, peduncles ſubgeminate one-flowered axillary, calyxes unequally toothed.]

15. Solanum Dulcamara. *Woody Nightſhade* or *Bitter-ſweet.*

S. africanum. *Mill. dict. n.* 26.
Stem unarmed fruteſcent flexuoſe, upper leaves haſtate, racemes cymed.

[16. Solanum triquetrum. *Triangular-ſtalked Nightſhade.*
Lin. ſpec. ed. Willd. 1. 1029. *Cavan. ic.* 3. 30. *t.* 259.
Stem unarmed fruteſcent three-ſided, leaves cordate acuminate ſmooth, umbels oppoſite to the leaves ſubpeduncled.

17. Solanum ſcandens. *Scandent Nightſhade.*
Lin. ſyſt. 224. *ed. Willd.* 1. 1029. *ſuppl.* 147.
Unarmed, ſtem twining, leaves cordate ovate hanging down very ſoft beneath, peduncles terminating.

18. Solanum lyratum. *Lyrate-leaved Nightſhade.*
Lin. ſyſt. 224. *ed. Willd.* 1. 1029. *Thunb. jap.* 92.
Unarmed herbaceous, erect, leaves lyrate-haſtate tomentoſe.

19. Solanum Tegore. *Guiana Nightſhade.*
Lin. ſpec. ed. Willd. 1. 1030. *Aubl. guian.* 1. 212. *t.* 84.
Stem unarmed ſhrubby very hirſute, leaves petioled, the lower pinnatifid-ſinuate, the upper cordate, racemes ſimple axillary.

20. Solanum quercifolium. *Oak-leaved Nightſhade.*
Lin. ſpec. 264. *ſyſt.* 223. *Reich.* 1. 511. *Willd.* 1. 1030.
Stem unarmed ſubherbaceous angular flexuoſe rugged, leaves pinnatifid, racemes cymed.

21. Solanum laciniatum. *Cut-leaved Nightſhade.*
Lin. ſpec. ed. Willd. 1. 1030. *Ait. kew.* 1. 247. *Curt. magaz. t.* 349.
S. aviculare. *Forſt. prodr. n.* 107. *eſcul. n.* 12.
Stem ſhrubby unarmed very ſmooth, leaves pinnatifid, ſegments lanceolate acute, panicles axillary by twos or threes.

22. Solanum radicans. *Rooting Nightſhade.*
Lin. ſpec. 264. *Reich.* 1. 512. *Willd.* 1. 1031. *Dec.* 1. *t.* 10.
Stem unarmed herbaceous even roundiſh proſtrate rooting, leaves pinnatifid, racemes cymed.

23. Solanum havanenſe. *Havannah Nightſhade.*
Lin. ſyſt. 223. *Reich.* 1. 512. *Willd.* 1. 1031. *mant.* 47. *Jacqu. amer.* 49. *t.* 35. *pict.* 29. *t.* 48. *Swartz obſ.* 82.
Stem unarmed fruteſcent, leaves oblong-lanceolate quite entire ſhining, racemes axillary.

24. Solanum triſte. *Dull Nightſhade.*
Lin. ſyſt. 223. *ſpec. ed. Willd.* 1. 1031. *Jacqu. amer.* 50. *t.* 40. *f.* 2. *pict.* 30. *t.* 49. *Vahl ſymb.* 3. 38.
Stem unarmed fruteſcent, leaves lanceolate-oblong ſubrepand ſmooth, racemes ſubcymed.

25. Solanum recemoſum. *Waved-leaved Nightſhade.*
Lin. ſyſt. 223. *Reich.* 1. 512. *Willd.* 1. 1031. *mant.* 47. *Jacqu. amer.* 50. *t.* 36. *pict.* 30. *t.* 50.
Stem unarmed fruteſcent, leaves lanceolate repand waved, racemes long ſtraight.

26. Solanum corymboſum. *Ovate-leaved Nightſhade.*
Lin. ſpec. ed. Willd. 1. 1031. *L'Herit. ſolan. t.* 3. *Jacqu. collect.* 1. 78. *ic. rar. t.* 49. *Ait. kew.* 1. 248. *Retz. obſ.* 5. 22.
Stem unarmed ſuffruticoſe, leaves ovate-lanceolate entire acuminate at the baſe, flowers corymbed.

27. Solanum quadrangulare. *Square-ſtalked Nightſhade.*
Lin. ſyſt. 224. *Willd.* 1. 1032. *ſuppl.* 147. *Thunb. prodr.* 36.
Stem unarmed fruteſcent four-cornered, leaves ovate entire and angular, flowers panicled.

28. Solanum repandum. *Repand-leaved Nightſhade.*
Lin. ſpec. ed. Willd. 1. 1032. *Forſt. prodr. n.* 105.
Stem unarmed ſubherbaceous flexuoſe even, leaves ovate repand tomentoſe, peduncles axillary cymed.]

29. Solanum bonarienſe. *Tree Nightſhade.*
Lin. ſpec. 264. *ſyſt.* 223. *Reich.* 1. 512. *Willd.* 1. 1032. *mant.* 205. *Dill. elth.* 364. *t.* 272. *f.* 351.
Stem almoſt unarmed ſhrubby, leaves ovate-oblong ſinuate-repand rugged.

30. Solanum macrocarpon. *Smooth fleſhy-leaved Nightſhade.*
Lin. ſyſt. 223. *Reich.* 1. 513. *Willd.* 1. 1032. *mant.* 205. *Mill. fig.* 196. *t.* 294. *Plum. ſpec.* 4. *ic.* 224. *f.* 2.
Stem unarmed ſuffruticoſe, leaves wedged repand ſmooth.

S. amer. fruticosum glabrum, foliis subrotundis subtus incanis, floribus racemosis. *Houst. Mss.*
Stem unarmed shrubby, leaves ovate quite entire tomentose underneath, umbels erect terminating, calyxes obtuse lanuginous.

DESCRIPTIONS, *&c.*

[1. This is an unarmed tree. Leaves a span long, quite entire, brown. Panicle solitary, dichotomous, composed of one-ranked racemes. Berries black.—Native of South America [k].

2. This is an unarmed tree, above the height of a man, with a trunk as thick as the human arm. The ends of the branches, the leaves, peduncles and calyxes are covered with a thick nap. Peduncles terminating, erect, always bifid, with the branches again bifid. Flowers white, inodorous [l].

Native of America, and, according to Loureiro, of Cochinchina. Jacquin found it in the mountain woods of Martinico, and says that it flowers there in november.]

According to Miller, it was sent by Catesby from the Bahama islands, but he confounds it with the *bahamense* of Dillenius, which is a prickly species. See n. 72. But his description belongs to this species. It rises with a smooth shrubby stalk six or eight feet high, covered with a brown bark, and divides into many branches, which have spear-shaped leaves three inches and a half long, and an inch and half broad; they have a few sinuated indentures on their edges, and end in acute points; they are smooth, and of a light-green colour. The flowers are produced in small umbels from the side of the stalks, standing erect; they are pretty large, white, and the petal is cut into five star-pointed segments.

[3. This is very like the preceding, but has the leaves very long-pointed, and differs in the stipules, the colour of the flower, and in having a shorter petiole [m].—Vahl says, that it differs only in having a pair of axillary leaflets.

Native of the islands of Madagascar, Mauritius and Bourbon. Introduced in 1773 by Monf. Richard. It flowers here in april [n].

4. This also resembles the second species, but differs in having the leaves pubescent decreasing at the base and smaller; the flowers raceme-umbelled; the racemes opposite to the leaves; the flower larger and purple.—Native of the East Indies [o].

5. This is a small upright tree about twelve feet high. The leaves when it is young are often a foot long. Flowers small, white, in racemes only half the length of the leaves.

Found by Jacquin in coppices of the island of Tierra Bomba near Carthagena in America [p].]

6. This rises with a strong woody stalk four or five feet high, and divides into many slender stiff branches, having spear-shaped leaves turning backward. The flowers are white, and grow in small umbels, or singly on the side of the branches, to which they sit close; they appear from june to september, and are succeeded by berries as large as small cherries, which ripen in winter. There are two varieties, one with red, and the other with a yellowish fruit. It is a native of the island of Madeira.

[Gerarde says, we have this rare and pleasant plant, called Tree Nightshade, in our gardens, rather for pleasure than profit, or any good quality as yet known. It is kept in pots and tubs in houses during the extremity of winter, and is set abroad in march or april. Parkinson says, that many gentlewomen call the fruit Winter Cherries; and this name has superseded the other.

7. Branches tomentose at the end. Leaves three or four inches long, an inch and half wide at the base, smooth, not at all repand, when young somewhat tomentose. Umbels many-flowered. Peduncle very short: pedicels an inch long. Corolla white, hairy on the outside. Anthers saffron-coloured. Berries smooth, red, a little larger than a pepper-corn.—It differs from the preceding in having broad quite entire leaves, the umbels peduncled, and the fruit only one third of the size. It may however be only a variety.—Native of Egypt.

8. Stems decumbent, branched. Branches round, warted, villose at top. Leaves petioled, two inches long, acute at both ends, simply veined, villose, especially underneath, waved and somewhat toothletted about the edge, ciliate: leaves on the branchlets oblong and more hairy. Peduncle terminating, erect, three inches long: umbels in threes, peduncled, alternate, having from seven to nine flowers: pedicels unequal, filiform, scurfy and villose, as are also the peduncles, calyxes and corollas. Calyx five-toothed: segments equal, lanceolate, obtuse, smooth within.—Native of Arabia Felix [q].

9. Branches herbaceous, round, villose below, above axillary, as are also the branchlets, tomentose with a ferruginous-yellowish-nap. Leaves very remote, two or three inches in length, two together on the branchlets, one several times smaller than the other, oblong or ovate, little attenuated, acute, those which are more advanced smooth above, and without veins, but paler beneath and veined; the younger ones have a ferruginous nap on them. Petioles half an inch long, ferruginous-tomentose. Peduncles axillary, two together, one a quarter of an inch long flowering first, the other shorter. Flowers drooping, ferruginous-tomentose. Calyx bell-shaped, short, truncate, ten-toothed: teeth linear, little shorter than the calyx itself. Corolla smooth, length of the peduncle.—Native of the island of Martinique [r].

10. This is an evergreen stinking shrub two or three feet high, with a trunk the size of a finger, woody round and blackish, and brown branches: the whole unarmed and smooth. Branches and leaves mostly stretched out horizontally. Most of the leaves two together, on short petioles, by the side of each other; one lanceolate, bluntish, entire, from two to four inches long, the other about an inch, obovate, very blunt, sometimes emarginate. Common peduncles very short, lateral, many-flowered, forming a sort of cyme; the proper peduncles pendulous at the back of the leaves. Flowers small, with a five-toothed calyx: corolla white, deeply five-parted; segments lanceolate, acute. Berry globular, smooth, succulent, orange-coloured, the size of a Chich-Pea. Seeds whitish-yellow. It flowers the whole summer, and the seeds ripen in winter [s].

Native of the West Indies. Cultivated by Mr. Miller in 1759 [t].

11. This also is a shrub, the height of a man and much branched. Trunk the size of a finger, round, having a blackish dotted bark. Branches mostly dichotomous, divaricating very much, the younger smooth, the older roughened. Leaves lanceolate, on very short petioles, alternate at the joints, quite entire, appearing smooth to the naked eye, but indistinctly villose when examined by a magnifier, two inches long. Peduncles from the forking of the branchlets or opposite to a leaf, solitary, one-flowered pendulous, slender, an inch long. Calyx small, bell-shaped, truncate, ten-streaked. Corolla wide, wheel-shaped, spreading very much, with a yellow five-rayed star, the acute points of which stretch out beyond the border. The flowers open about five o'clock in the morning and close in a short time, remaining so for a few days and then falling off. Anthers yellow. Style longer than the stamens, awl-shaped, thick, white. Stigma yellow. Native of the Caracas [u].

12. This is an unarmed shrub, with round smooth branches, appearing slightly mealy at top when examined

with a magnifier. Leaves alternate, two inches long, attenuated, acute, ſmooth on both ſides, obſcurely veined, on ſmooth petioles half an inch in length. Peduncles firſt four, then two, growing out farther along with the branchlet, filiform, one flowering firſt, the length of the petiole, the other ſhorter. Calyx ſmooth, ſubcampanulate, three times ſhorter than the corolla, ten-toothed: teeth linear-ſubulate, equal. Corolla ſmooth. This and the next ſpecies approach to S. fugax.—Native of Cayenne, where it was found by von Rohr.

13. Stem ſeeming to be twining, ſhrubby, unarmed. Branches round, ſmooth, flexuoſe, even: branchlets axillary, alternate, bent back as if broken, rigid, bearing leaves and flowers at the top, ſometimes forked. Leaves alternate, attenuated, quite entire, ſimply and obſcurely veined, an inch and half long, often two at the end of the branchlets, one ſmaller than the other. Petiole ſhorter by half than the branchlet. Peduncles filiform, an inch long or rather leſs, aggregate, axillary, four, at the ends of the branchlets five or ſix, one-flowered. Calyx truncate, entire, ſmooth. Corolla five-cleft, three times as long as the calyx: ſegments ovate.—Allied to S. geminatum, but differing in having ſtouter branchlets bent back as if broken, more peduncles, toothleſs calyxes, and ſmaller flowers. Native of South America [x].

14. This is a ſhrub higher than a man, evergreen, weak, ſcandent, ſmooth and unarmed. Stems ſeveral, the thickneſs of a reed or of a finger, brown, ſpringing from a brown root as big as the fiſt. Branches numerous, round, divaricating. Leaves alternate, lanceolate or ovate-lanceolate, acuminate, quite entire, on ſhort petioles, bright green, from two to four inches long. Peduncles one-flowered, axillary, moſtly two together, ſometimes three or only one, ſlender. Flower elegant but without ſcent. Calyx ſmall, obtuſe, and cut into many unequal parts. Corolla large, ſpreading very much, thin, rounded, blue with a five-rayed ſtar, green and protuberant beneath ſo as to be like a calyx and exterior corolla; its acute points ſtretch beyond the border. Anthers yellow. Style green. Stigma capitate, bifid. Berry globular, the ſize of a pea [y].

According to Willdenow, it ſeems to differ from the preceding, to which it is allied, in the ſize of the flower, and in the calyx. In his ſpecimen the peduncles are in twos, threes and fours, always axillary, without any terminating ones, and the calyx is four, five or ſix-toothed, with the teeth unequal.

15. Root perennial, woody, according to Dr. Beddoes, ſmelling like the Potato. Stem ſhrubby, roundiſh, branched, twiſted and climbing to the height of ſeveral feet. Leaves alternate, petioled, ovate-lanceolate, quite entire, ſmooth, ſoft, veiny; the lower cordate, the upper more or leſs haſtate. Flowers in racemes or cyme-ſhaped panicles, but not properly in cymes, oppoſite to a leaf or terminating, nodding, very elegant, purple with two green dots at the baſe of each ſegment, and the ſegments reflexed. Anthers large, yellow or lemon-coloured and connate. Berries elliptic, ſcarlet, very juicy, bitter and poiſonous [z]. Seeds flat, ſomewhat kidney-ſhaped, of a yellowiſh colour. The ſtem is thinly ſet with ſmall pointed tubercles. The younger branches are often purple. The proper peduncles are bulbous at the baſe, or grow out of a kind of ſocket. The calyx is purpliſh, with blunt ſegments. The mouth of the corolla is dark and ſhining, and the ſegments are lanceolate. The filaments are very ſhort and of a dark purple colour. The anthers have two holes at the top of each, out of which the pollen is diſcharged [a]. At the firſt opening of the flower they are readily ſeparable, but afterwards growing drier, they will ſooner tear than be diſjointed [b].

Native of Europe, Africa and Siberia, in moiſt hedges, ſhady places and the ſides of ditches; flowering in june and july. The berries are ripe in ſeptember and october.

The roots and ſtalks of Woody Nightſhade, upon being chewed, firſt cauſe a ſenſation of bitterneſs, which is ſoon followed by a conſiderable degree of ſweetneſs; whence this plant obtained the names of Dulcamara and Bitterſweet. The berries excite vomiting and purging [c]. Floyer ſays that thirty of them killed a dog in leſs than three hours, remaining undigeſted in his ſtomach. As they are common in hedges, and may be miſtaken by children for red currants, this circumſtance is the more worthy of notice. In ſuch a caſe it is adviſeable to pour down as much warm water as poſſible, to dilute the poiſon and provoke vomiting, till farther aſſiſtance can be had.

The old botaniſts recommend this plant as a medicine in many diſeaſes. Ray informs us, that the inhabitants of Weſtphalia, make uſe of a decoction of the whole plant as their common drink, with ſucceſs againſt the ſcurvy [d]. Boerhaave ſays, it is a medicine far ſuperior to China and Sarſaparilla, as a ſweetener and reſtorative: and Linneus, that an infuſion of the young twigs is an admirable medicine in acute rheumatiſms, inflammations, fevers, and ſuppreſſion of the lochia. Dr. Hallenberg adviſes it in iſchiatic and rheumatic pains, jaundice, ſcurvy, and lues venerea. They direct a pint of boiling water to be poured upon two drams of the ſtalks ſliced and dried; after ſtanding half an hour, it muſt be boiled ten or fifteen minutes. The doſe is two tea-cups full or more morning and evening [e]. Haller obſerves that the Dulcamara partakes of the milder qualities of common or garden Nightſhade, joined to a reſolvent and ſaponaceous quality. Murray and Bergius regard it as promoting all the ſecretions. The latter confines its uſe to rheumatiſm and retention of the menſes and lochia. But according to other good authorities, it has been applied with advantage in ſome obſtinate cutaneous affections.—Dr. Cullen ſays, we have employed only the ſlender twigs, but ſome parcels of theſe were very mild and inert, others conſiderably acrid. In the latter ſtate we have employed a decoction of them in the cure of rheumatiſm, ſometimes with advantage, but at other times without any effect. Though the Dulcamara be inſerted in the catalogue of diuretics, it has never appeared to us as powerful in this way; for in all the trials made here, it has hardly ever been obſerved to be in any meaſure diuretic. The twigs ſhould be gathered either in ſpring or autumn, but will be found moſt powerful in the latter ſeaſon. If uſed dry, a ſomewhat larger doſe muſt be taken. This plant is generally given in decoction or infuſion; and to prevent its exciting vomit, it ſhould be diluted with milk; ſmall doſes alſo are recommended at the beginning, for large ones have been found to produce convulſions, delirium, and palſy of the tongue [f]. Mr. Saunders, author of an elegant introduction to Botany, publiſhed in 1792, has, in the courſe of an extenſive country practice, uſed the Dulcamara with great ſucceſs, and without the inconveniences juſt mentioned [g].

β. It is ſometimes found with fleſh-coloured and with white flowers.] Miller ſays, the leaves of this are woolly, and that the difference is conſtant.

[γ. On the ſea coaſt it has the leaves hairy, according to Hudſon. Ray ſays, that Dr. Brown, fellow of Magdalen College, Oxford, a very ſkilful botaniſt, confirmed to him that this plant differed from the common Woody Nightſhade in its whole habit.—Lhwyd found it near Uyſni river in Caernarvonſhire; but it is on the ſouthern coaſts of our iſland in many places [h].

δ. Willdenow affirms, that Dillenius's African Sol. Dulcamara is without doubt a diſtinct ſpecies. The flowers are larger, opening only about noon, of a paler colour, the ſegments leſs acuminate and not reflexed; the branches end in many peduncles, dichotomouſly divided and ſubdivided; towards the top they are angular and rough, below they are round, hairy and leſs rough. Leaves on the flowering-branches ſmaller, pointed at both ends and entire; on the barren branches bigger, and wider at the baſe, the lower ones entire

and roundiſh, the upper angular, not unlike thoſe of Ivy: both alternate, frequent, thick, rigid, ſet all over with abundance of hairs, ſo ſhort as to be felt rather than ſeen, green on both ſides, here and there tinged with duſky purple; veins few ſpringing obliquely from the midrib. None of the leaves appear to be haſtate, by the figure.

Native of the Cape of Good Hope. It was ſent from Holland to Sherard's garden at Eltham, where it was cultivated about 1726 [f].]

Mr. Miller remarks that the leaves are ſhorter, thicker and more indented.

Beſides theſe varieties, there is one with variegated leaves, which is preſerved by thoſe who are curious in collecting ſtriped-leaved plants.

[16. Stem ſpread on the ground, branched, four feet long, moſtly tender and ſmooth, as is the whole plant. Leaves alternate; the lower ovate-acuminate; the upper cordate-lanceolate; commonly hanging down: petioles ſeveral times ſhorter than the leaves. Flowers hanging down in umbels, on a very ſhort bifid peduncle: the pedicels half an inch in length. Corolla white, very deeply divided into five linear curled ſegments. Berries globular, the ſize of a pea, pendulous. It flowers in the royal garden at Madrid in ſeptember [k]. Willdenow remarks, that the umbel is very ſhortly peduncled and four-flowered.

17. Stem herbaceous, round, twining. Leaves alternate, petioled, ovate or cordate, remote. Raceme terminating, compoſed of three or four ſimple ones. Calyx ſcarcely divided. Corolla wheel-ſhaped, with the petals lanceolate and recurved. Anthers erect, perforated at the top. Berry globular, the ſize of a Cherry, with a ſhort calyx, contracted and gibbous under the fruit with five ſwellings.—Native of Surinam, where it was found by Dahlberg [l].

18. The whole plant is cloſely and darkly tomentoſe. Stem round, little flexuoſe, with a few alternate branches. Leaves ſcattered, ovate, the lower ones lyrate-pinnatifid, the upper haſtate, an inch long, the lateral ſegments almoſt oppoſite, four ſeldom more, entire, the end one larger, acuminate, entire. Petiole a little ſhorter than the leaf. Flowers axillary towards the top, and terminating, in a ſubdichotomous panicle. Pedicels and calyx ſmooth. Anthers yellow, perforated.

Native of Japan near Nagaſaki; flowering in ſeptember and october [m].

19. This is a plant five or ſix feet high, with a woody round ſtem, having trichotomous branches, and forming a thick buſh. Leaves alternate, the lower ones very large and wide, divided into ſeveral broad acute lobes; the largeſt are fifteen inches long and ten wide; they are green and ſoft: petiole cylindric, two inches long. Leaves on the branches cordate, ending in a point, downy like the others: the largeſt of theſe are ſeven inches long and three inches wide: petiole an inch in length or a little more. Flowers between the forks of two branches, very ſmall, many together on a common villoſe peduncle; pedicels very ſhort. Corolla deeply divided into five narrow ſharp ſegments. Berries globular, yellowiſh, almoſt the ſize of a walnut. Seeds flatted and rounded. All parts of the plant exhale a very diſagreeable odour.

Native of Guiana, by the banks of the river Sinemari; flowering and fruiting in october. Called Tegoré by the Galibis [n].

20. This is ſiſter to S. Dulcamara. Stems angular, erect, rugged. Leaves oblong, decurrent into the petiole, veined, ſmooth, rugged beneath, pinnatifid. Peduncles branched. Corollas violet-coloured, blunter than in Dulcamara, with two greeniſh ſpots at the baſe of each lobe. Anthers yellow, ſhorter than the ſtyle. Berries ovate [o]. It reſembles S. radicans (n. 22.) but differs in having the leaves rugged, the ſtem erect, the flowers panicle-corymbed and much larger [p].

Native of Peru. Introduced in 1787, by Monſ. Vare. It flowers in july [q].

[f] Dill. elth. [k] Cavanilles. [l] Linn. ſuppl.
[m] Thunberg. [n] Aublet. [o] Linn. ſpec.
[p] Willdenow. [q] Hort. kew.

21. Leaves ſmooth almoſt as in Lactuca perennis. Flowers violet-coloured, the ſame ſize as in Geranium pratenſe, with the ſegments of the corolla emarginate. Anthers ſeparate, not cohering as in moſt of the ſpecies. Berries yellowiſh-green, the ſize of a ſmall Plum [r].

Native of New Zealand, where it was found by Sir Joſeph Banks, and was introduced in 1772. It flowers in july and auguſt [s].

Mr. Curtis, who cultivated and figured it, obſerves that it is a plant of ſome beauty, and remarkable for receding from the common character of the genus, in having the anthers widely ſeparate from each other: alſo that the pulp of the berries is ſweet, taſting in a ſmall degree like a Fig.

S. aviculare of Forſter is ſuppoſed to be the ſame with this. He deſcribes the berries as fulvous, the ſize of a large Plum, acid, with little ſweetneſs and ſomewhat mawkiſh. The natives of New Zealand devour them greedily; birds are very fond of them; and the Europeans did not entirely diſdain them.—The ſtem is upright, branched, and a yard high: the branches herbaceous, ſmooth, roundiſh, nearly the ſize of a finger, and ſhort. Leaves alternate, ſinuate-pinnatifid, a foot long, compoſed of three pairs of oppoſite, ſmooth, entire ſegments, of a deep green colour. Petioles ſemicylindrical, ſmooth, ſpreading, ſcattered. Corymbs terminating, two or three, few-flowered. Peduncle roundiſh, upright; pedicels ſix or ſeven, ſcattered, one-flowered, round, ſmooth, ſpreading, proportional in height, jointed as it were into the peduncle. Flowers an inch in diameter, purple with yellow anthers [t]. Forſter does not notice the ſeparation of the anthers, but ſays that they converge into a tube.

22. This plant agrees with S. quercifolium in many circumſtances, but differs in the following.—The ſtem is diffuſed, rooting and ſmooth; the leaves are ſmooth; the leaflets five and ovate; the racemes ſimple and few-flowered; the flowers ſmaller, white purpliſh beneath and not ſpotted; the berries globular, twin, yellow.—Native of Peru [u]. Introduced in 1771, by Monſ. Richard. It flowers in july and auguſt [x].

23. Stem ſhrubby, three or four feet high, with upright, round, ſmooth branches. Leaves alternate, petioled, oblong, wedged at the baſe, with a ſhort blunt tip, entire, nerved, ſmooth on both ſides, pale beneath, thicker. Racemes terminating, ſolitary, containing from four to ſeven flowers. Peduncles one-flowered, ſhort. Calyx parted half way; ſegments oblong, permanent, white at the edge. Corolla biggiſh, blue; the border half-five-cleft and ſpreading, the ſegments wide and plaited. Filaments very ſhort. Anthers converging, yellow, having two pores at the top [y].

According to Jacquin, it is an upright ſhrub, five feet high, with few branches. Peduncles two or three-flowered, lateral, few. Flowers handſome, but without ſcent, almoſt an inch in diameter, ſpreading very much, having ſcarcely any tube, the border divided into very ſhort wide ſegments, emarginate with a point. Anthers thick, blunt at each end, not contiguous. Berry ovate, ſhining bright, deep blue, containing a little watery juice but hardly any pulp. Seeds kidney-form, compreſſed, faſtened to a fleſhy-pulpy receptacle, which grows on each ſide along the middle of the partition. In habit and fructification it is between Solanum and Capſicum.

Found at the Havanna by Jacquin, flowering in january; and by Swartz in Jamaica, flowering in june. He ſays that Jacquin's figure is not a very good one.

24. This is an upright ſhrub, eight feet high and not handſome. Leaves acute, dark green, petioled, alternate, ſeven or eight inches long. Racemes lateral, thick, an inch and half long, ſimple or bifid, warted with the falling off of the pedicels that firſt come out. Flowers ſmall, white, forming a ſort of cyme. Berries globular, of a dirty yellow colour [z].

Vahl ſays that the branches are round and ſmooth:

[r] Willdenow. [s] Hort. kew. [t] Forſt. eſcul.
[u] Linn. dec. [x] Hort. kew. [y] Swartz. [z] Jacquin.

the

Digitized by Google

the leaves elliptic-lanceolate, nerved and veined, running a little down the petiole, entire or obſcurely repand. Peduncles lateral, an inch long, many-flowered. Calyx ſhort and ſmooth, with rounded ſegments. Diviſions of the corolla lanceolate.—Native of Martinique.

25. This is a branching upright ſhrub, four feet high. Leaves ſhining, petioled, alternate. Racemes ſimple, lateral, erect, the length of the leaves; the pedicels erect in the flower, pendulous in the fruit. Flowers without ſcent. Corolla ſnow-white, cut very deeply into lanceolate-oblong ſegments. Berries red, the ſize of a ſmall pea [a].

Linneus remarks, that it reſembles S. bahamenſe very much.—Native of the Weſt Indies. Introduced in 1781 by Mr. Francis Maſſon [b].

26. Stems ſeveral, the thickneſs of a reed or more, round, woody and perennial at bottom, herbaceous and annual above, branched, erect or weak and decumbent, having the habit of S. Dulcamara. Leaves ſmooth, acute, alternate, fetid. Racemes oppoſite to the leaf, ſlender, bifid, trifid or quadrifid, many-flowered, ſhorter than the leaves. Flowers ſmall. Corolla blue: ſegments both of that and the calyx bluntiſh. Berry orange-coloured, the ſize of a ſmall pea. Seeds few, pale [c].

Native of Peru. Introduced in 1786, by Monſ. Thouin. It flowers in july [d].

According to Retzius, the ſtem is two feet high, ſuffruteſcent, weak, angular, naked, becoming ſhrubby in the ſtove. Leaves ſcattered, ovate, naked, moſtly entire but ſometimes three-lobed; in the ſtove lanceolate. Cymes from the upper axils, ſhort, formed of ſimple and compound racemes. Flowers ſmall, purple. Berries ſmall, black.

27. This differs principally in having a four-cornered hirſute ſtem. The leaves are often decurrent and thus the corners of the ſtem are curled. It varies with lanceolate entire leaves.—Native of the Cape of Good Hope [e].

28. Native of the Marcheſas and Society Iſles [f].

29. Stem ſhrubby, a fathom high and more, almoſt unarmed, having only a few prickles on the ſtem when it is tender, flexuoſe, brown. Leaves deltoid, ſubrepand, lanceolate, wide, naked, rugged. Peduncles lateral, ſubquinquefid, ſubumbelled. Flowers white, large, nodding, tomentoſe on the outſide. Anthers yellow. Berries of the ſame ſize as thoſe of Sorbus aucuparia or Mountain Aſh [g].]

Stem woody, ten or twelve feet high, covered with a purpliſh bark almoſt ſmooth. At the top it divides into ſeveral branches which grow erect. Leaves wedge-ſhaped, ſinuated. Flowers in large umbels at the end of the branches, large and white; the petal is angular, but not divided at the brim. Berries ſmall, yellow when ripe.

[Native of Buenos Ayres. Cultivated in 1727, by James Sherard, M. D.[h] It was raiſed in the Eltham garden from berries on a dried ſpecimen ſent from Buenos Ayres, and flowered the year above mentioned, in ſeptember, the year following it flowered ſooner, and the third year in june [i].

30. Stem ſtiff, a foot high, the thickneſs of a finger, perennial, even. Branches annual, erect. Leaves oleraceous, large, obtuſe. Flowers large, blue, bell-ſhaped, erect, on ſhort pedyncles, many of them barren. Berries the ſize of an apple, globular, yellow, ſubſeſſile [k].

Stem taper and ſmooth, of a deep green colour when young, but afterwards the lower part becomes woody, and has a brown bark. It riſes from two to three feet high, and ſends out branches irregularly on every ſide. Leaves oblong-ovate, ſmooth, four or five inches long, and three inches broad in the middle, irregularly ſinuate, ending obtuſely, of a deep-green colour, on ſhort foot-ſtalks, placed without order on the branches. Peduncles axillary, ſhort, having frequently two ſmall leaves below the flowers, which are generally cluſtered together at the top, ſitting cloſe to the foot-ſtalks. Flowers large, of a fine blue colour, ſpreading almoſt flat, and having five corners. Anthers oblong, orange-coloured. Fruit roundiſh, ſmooth, almoſt as large as a walnut, of a deep-green colour, changing when ripe to a pale yellow. It begins to flower in june, and there is a ſucceſſion of them till winter [l].—Native of Peru. Cultivated in 1759, by Mr. Miller [m].

31. The Potato is well known for its tuberous root. Stem from two to three feet in height, ſucculent, ſomewhat angular, ſtriated, ſlightly hairy, frequently ſpotted with red, branched; the branches long and weak. Leaves interruptedly pinnate, having three or four pairs of leaflets, with ſmaller ones between, and one at the end larger than the reſt; the leaflets are ſomewhat hairy, and dark green on the upper ſurface. The flowers are either white or tinged with purple; or, as old Gerarde deſcribes them, of a light purple, ſtriped down the middle of every fold or welt with a light ſhow of yellowneſs. The fruit is a round berry, the ſize of a ſmall plum, green at firſt, but black when ripe, and containing many ſmall flat roundiſh white ſeeds.

The Potato, now ſo generally cultivated in Europe, appeared at the end of the 16th century, as a curioſity in botanic gardens. Gerarde (in 1597) informs us, that he received roots of it from Virginia, otherwiſe called Norembega, which grew and proſpered in his garden, as in their own native country. He calls it Potato of America or Virginia, to diſtinguiſh it from the Spaniſh Potato (Convolvulus Batatas), which was then much better known, and called excluſively Potatoes, Potatus, or Potades, from the Spaniſh name Battata [n].

Though it be pretty clear that the Potato came to us from Virginia, yet it does not follow that it is originally indigenous of that country; but it is more probable that it is a native of Peru, whence the Spaniards might have it immediately. Pet. Cieca, Gomara and Acoſta inform us, that in the neighbourhood of Quito there is a plant with tuberous roots, called Papas, of which the inhabitants make a ſort of bread, and that they alſo eat them both boiled, and roaſted in the embers. Theſe are ſuppoſed to be, not the Spaniſh, but our common Potato: as alſo thoſe which the Virginians call Openanck or Openawk.

The Potato which was ſo common in Italy in and before the 16th century was doubtleſs the Spaniſh or Convolvulus Batatas; for it is ſaid to have been eaten as commonly with mutton as Turneps or Parſneps, and even to have been uſed for feeding hogs. If this had been our common Potato, how, as Cluſius remarks, could the knowledge of this root have been ſo late in coming to us; and how could they have been ignorant of it at Padua, till he ſent it to them from Frankfort.

Cluſius himſelf owed his firſt acquaintance with the Potato to Philip de Sivry, Lord of Walhain, &c. in Flanders, who ſent him two roots, with the fruit, to Vienna, in the beginning of the year 1588, and the year following, a drawing of a branch with the flower. De Sivry had it the year before from a friend of the Pope's Legate in Flanders, under the name of Tartufoli, by which appellation the Italians diſtinguiſh all roots that are tuberous like Truffles. James Garet, junior, alſo ſent Cluſius a drawing of the whole plant, but the figure which this celebrated botaniſt gives in his Rariorum Plantarum Hiſtoria (1631), is from a living plant in his own poſſeſſion [o].

Caſpar Bauhin (in prodr.) relates, that he had a coloured drawing of the plant from Scholtz, in 1590, under the name of Pappas Hiſpanorum. Not finding any deſcription of it, he deſcribed and figured it in his Phytopinax and in his edition of Matthiolus. He alſo ſent the figure to Cluſius, who however does not mention having received it from Caſpar Bauhin. This celebrated author ſays that the Solanum tube-

[a] Jacquin. [b] Hort. kew. [c] Jacquin. [d] Hort. kew. [e] Linn. ſuppl. [f] Forſter. [g] Linn. mant. [h] Hort. kew. [i] Dill. elth. [k] Linn. mant. [l] Mill. fig. [m] Hort. kew. [n] Flora ruſtica. [o] Cluſ. hiſt.

roſum

roſum eſculentum came from Virginia into England, and thence into France and other countries[p].

Liſter, in his journey to Paris (10th Dec. 1698) informs us, that the Potato was then ſcarcely to be found in the French markets, which was ſo great a relief to the people of England: but that there was ſtore of Jeruſalem Artichokes[q]: which root ſeems to have been almoſt as commonly cultivated in England at the end of the 16th and the beginning of the 17th century, as the Virginian Potato has been in the 18th.

It was cultivated in France about the year 1742: but in 1749 it was treated with great contempt both in the country and at Paris, and left wholly to the lower people. Afterwards however it became quite the faſhion for a time, and then fell again into diſrepute. In 1771 Monſ. Faiguet preſented to the Academy of Sciences a loaf of bread made of Wheat, Rie and Potatoes in equal quantities. In 1778, Monſ. Parmentier made bread of Potatoes only. In 1781, biſcuit was made of them by Monſ. Parmentier the younger[r].

The Potato made its fortune in Germany much ſooner. For Cluſius ſays, in the year 1601; "ea plerisque Germaniæ hortis ſatis vulgaria dudum facta." Bread is ſaid to have been made with it there ſo early as 1731. I ſaw it extenſively cultivated in the open fields of Suabia in 1780.

In Italy the Potato has never been much eſteemed; nay the prejudice againſt it was ſo great, that when a ſhip-load of the roots was ſent from England ſome years ſince to Naples, to relieve the inhabitants in a famine, it is ſaid that the people choſe rather to ſtarve than to purchaſe them. They have however ſince grown wiſer, at leaſt in the northern parts of that country.

The Potato was certainly introduced into Ireland and England towards the end of the 16th or at the beginning of the 17th century, and was cultivated to conſiderable extent by the middle of the 17th. Sir Lucius Obrien aſſured Mr. Arthur Young, that there was no doubt of its having been in Ireland long before the time of Sir Walter Ralegh: and it is even ſaid, that venerable Bede, or ſome other old writer, gives a deſcription of the food of the common Iriſh in ſuch terms as are applicable to nothing but Potatoes. Some attribute their introduction to Sir Francis Drake, who died the 28th of january, 1590, aged fifty: others to Captain John Hawkins, ſo early as 1565, from Santa Fe[s]. There ſeems to be little or no authority for the above aſſertions; and as to the laſt, the Potatoes of Hawkins were certainly Convolvulus Batatas or Spaniſh Potatoes, as may be ſeen from Hawkins's own account of them in Hakluyt[t].

Mr. Miller ſays the Potato was firſt introduced from America about the year 1623. I am at a loſs to conceive why he has aſſigned ſo late a period to its introduction, when it is plain that it was cultivated by Gerarde in 1597. Dr. Campbell (polit. ſurv. 2. 95.) ſays, it appears that it was brought into Ireland about the year 1610.

The moſt probable account ſeems to be, that the celebrated and much to be lamented Sir Walter Ralegh firſt introduced this very uſeful root into Ireland on his return from Virginia in 1584. In Gough's edition of Camden's Britannia, it is expreſsly affirmed, that Sir Walter planted them at Youghall in the county of Cork[u]; where he had an eſtate. In Holt's characters of the Kings and Queens of England, is an apocryphal account of Sir Walter's miſtaking the fruit for the part that was to be eaten, and deſpairing of his acquiſition upon finding that to be unpalatable; but that he afterwards diſcovered the root to be grateful and nouriſhing, on ordering the ground to be turned over. We have alſo the old ſtory ſo often told of other vegetables, that they came into Lancaſhire, by the accidental ſhipwreck of a veſſel.

[s] Holt's characters of the Kings of England, vol. 3. Gentl. mag. for 1789, p. 437.
[t] Vol. 3. p. 507.
[u] Ibid. See Smith's ancient and preſent ſtate of Cork.

Nearly the ſame account is given by Profeſſor Matthias Chriſtian Sprengel, in his book on the origin of the Negro Slave Trade[x].

There is an evident incongruity in theſe two accounts, that the Potato was firſt imported into Ireland by Hawkins in 1565, and planted there by Sir Walter Ralegh. And we know that Hawkins's Potatoes were not the Solanum, but the Convolvulus Batatas, a totally different plant; as was mentioned above.

Better authority than theſe may be derived from the minutes of the Royal Society of Dec. 13, 1693, where it is ſaid:—"the Preſident (Sir Robert Southwell) related that Potatoes were brought into Ireland by his grandfather, who had them from Sir Walter Ralegh, after his return from Virginia:" this was in the year 1584; and that great man was beheaded in 1618.

It is generally agreed that the Potato quickly paſſed over from Ireland into Lancaſhire, where it has been cultivated ever ſince with extraordinary diligence, and improvement, both as to the time of coming to market, and the ſuperior excellence of new varieties raiſed from ſeed.—It is ſaid to have been forty years before it was much planted about London, and then it was conſidered merely as a rarity[y].

Parkinſon, in 1629, ſays that Potatoes of Virginia, are dreſſed in the ſame ways as the Spaniſh kind: that is, being roaſted under the embers, peeled and ſliced, they were put into ſack with a little ſugar; or they were baked with marrow, ſugar, ſpice, &c. in pies; or they were preſerved and candied by the comfit-makers; and thus dreſſed were eſteemed almoſt as delicate as the former[z]. This author mentions three ſorts of Potatoes, as well known among us, the Spaniſh, the Virginian, which ſome fooliſhly call the Apples of youth, and the Canadian, which ſome ignorant and idle head has called Artichokes of Jeruſalem. Much of the hiſtory and qualities of the firſt has been attributed to the ſecond.

Muffet, in 1655, ſays that Potado roots are now ſo common and known amongſt us, that even the huſbandman buys them to pleaſe his wife[a].

Soon after this the importance of this root was ſo well underſtood, that at a meeting of the Royal Society, march 18th, 1662-3, a letter was read from Mr. Buckland, a Somerſetſhire gentleman, recommending the planting Potatoes in all parts of the kingdom, to prevent famine. This was referred to a Committee, and in conſequence of their report Mr. Buckland had the thanks of the Society; ſuch members as had lands were entreated to plant them, and Mr. Evelyn was deſired to mention the propoſal at the cloſe of his Sylva[b].

I do not find that this truly patriotic gentleman complied with this deſire, or that he has mentioned the Potato, except in the Appendix to his Acetaria: where he ſays that the ſmall green fruit, being pickled, is an agreeable Sallet. But the root being roaſted under the embers, or otherwiſe, opened with a knife, the pulp is buttered in the ſkin, and ſeaſoned with a little ſalt and pepper. Some eat them with ſugar together in the ſkin, which has a pleaſant crimpneſs. They are alſo ſtewed and baked in pies, &c.

Worlidge, in 1687, ſays, that Potatoes are very uſual in foreign parts, and are planted in ſeveral places of this country to a very good advantage. He adds, I do not hear that it hath been as yet eſſayed, whether they may not be propagated in great quantities for food for ſwine or other cattle.

Potatoes, ſays Houghton, were firſt brought out of Virginia by Sir Walter Ralegh, and he ſtopping at Ireland, ſome were planted there, and thrived very well and to good purpoſe; for in their ſucceeding wars, when all the corn was deſtroyed, this ſupported them. From thence they were brought to Lancaſhire, where (in 1699) they are very numerous, and

Digitized by Google

now they begin to ſpread all the kingdom over. They are a pleaſant food boiled or roaſted, and eaten with butter and ſugar[c].]

Mr. Miller's account is, that this plant has been much propagated in England within thirty or forty years paſt, although it was introduced from America about the year 1623, yet it was but little cultivated in England till of late; theſe roots being deſpiſed by the rich, and deemed only proper food for the meaner ſort of perſons; however they are now generally eſteemed by moſt people, and the quantity cultivated near London exceeds, I believe, that of any other part of Europe.

[This was written in 1759, which carries the culture of the Potato to any extent, as far back as about the year 1720. But it ſeems more probable, as well as more conſonant to the accounts we have in various authors, that this uſeful root, like Turneps and Clover, was diffuſed gradually in Great Britain, after its firſt introduction from Ireland into Lancaſhire; though it muſt be confeſſed that notwithſtanding what Muffet ſays of its being common in 1655, it does not ſeem to have made much progreſs during the Commonwealth, when Clover, Turneps, &c. were ſo forcibly recommended by the writers on huſbandry. Neither Bligh nor Markham made mention of it; and Hartlib, in the Appendix to his Compleat Huſbandman, (1659) Alphabet of Interrogatories relating more particularly to Ireland, has only theſe words—" Potatoes. Where " any ſtore ſowen, when brought over firſt; and by " whom; what uſes made of them, what time to be " taken up, and how to be preſerved?"

Mr. Ray, in 1686, ſays no more of the Potato, than that the roots are dreſſed in the ſame manner as Spaniſh Potatoes.

Sharrock, in 1672, enumerates Potatoes among thoſe plants that may be propagated by offsets.

It is apparent that this uſeful root had little reſpect paid it in the 17th century: for Mr. Evelyn, in his Kalendarium Hortenſe, under february, ſays, " Plant " Potatoes in your worſt ground:" and under novem- " ber—take up your Potatoes for winter ſpending, " there will enough remain for a ſtock, though never " ſo exactly gathered[d]."

Edward Liſle, Eſq. whoſe obſervations on huſbandry were made in 1694 to the time of his death in 1722, has made no mention of the Potato. And Mortimer, in 1708, only inſerts it in his Monthly Kalendar, to be ſown in february; and ſays the root is very near the nature of the Jeruſalem Artichoak, but not ſo good or wholeſome, and that it may prove good food for ſwine[e].

Bradley, in 1720, ſpeaks of Potatoes as roots of leſs note than Horſe-Radiſh, Radiſh, Scorzonera, Beets and Skirret; but as they are not without their admirers, he will not paſs by the method of their culture in ſilence[f].

London and Wiſe, in the Complete Gard'ner, publiſhed in 1719, do not ſo much as mention the Potato[g].

All this ſerves to ſhow, that it was not attended to as it deſerved till the 18th century was conſiderably advanced. I can well remember, that about the middle of the century, it was wholly unknown as an eſculent root in many parts of the country, that even in and about London it did not generally make its appearance at table, and that it was not uſed at all by the common people or in feeding of cattle.

John Billingſley, Eſq. the reporter for Somerſetſhire under the Board of Agriculture, publiſhed in 1798, ſays that " thirty or forty years ago, it was an " extraordinary thing to ſee an acre of Potatoes in one " ſpot, and in one man's poſſeſſion; whereas there " are now many pariſhes in that county which can " produce fifty acres. Nay that the writer of the " report has grown thirty or forty acres for ſeveral " years ſucceſſively, and once had upwards of a hun- " dred acres in one year."

The Suffolk reporter, Arthur Young, Eſq. Secretary to the Board (1797) informs us that " this root has not been cultivated in that county till within a few years; that he has had it on a large ſcale, and Mr. Mure, of Saxham, on a larger; that in general Potatoes are not much attended to, but that they increaſe and promiſe to be much better eſtabliſhed; that the Rev. Mr. Nesfield, of Wickhambrook, has earneſtly preſſed the culture of it on his pariſhioners for near forty years, with little effect till lately."

In the North Riding of Yorkſhire, ſays Mr. Tuke, the reporter for that diſtrict (1800). " Potatoes firſt became an object of field huſbandry here not more than forty years ſince; before which time they were little known beyond the garden of the gentleman; within that period they have got univerſal poſſeſſion, from the table of the rich to the daily board of every cottage; with all the lower orders, they conſtitute the moſt eſſential article of their ſuſtenance; and at this time there is not probably one article, the produce of the country, that could not with leſs inconvenience be ſpared than the Potato, ſo univerſal is its uſe, ſo cheap and nutritious the food that it affords."

We may therefore ſafely affirm that it was not till ſome time after the middle of the 18th century, that the Potato came to be generally uſed as an eſculent root through the greater part of England.

In the year 1796, it was found by inquiries made in each pariſh, that about ſeventeen hundred acres were cultivated for the ſupply of the London markets, chiefly in Barking, Little Ilford, Eaſtham, Leyton and Weſtham, in the county of Eſſex. In the laſt pariſh alone five hundred acres were cropped with them[h]. Beſides theſe, large quantities are imported into London from Hull and other places.

As the 18th century advanced to a cloſe, the uſe of the Potato became general among all ranks of people; and two ſcarce years (1795 and 1799) have rendered its utility ſo conſpicuous, that it is now cultivated by farmers and cottagers in moſt parts of the kingdom.

Dr. Chriſtopher Merrett, whoſe work was publiſhed in 1667, ſays that Potatoes were then planted in many fields in Wales[i]. He does not inform us in what parts of the principality. In the agricultural reports for North Wales (1794), I find that in Flintſhire Potatoes are planted, where the ſoil admits, as a preparation for Wheat; that in Angleſey they are imported from Ireland; that in Caernarvonſhire they are cultivated on a ſmall ſcale; and in Merionethſhire, leſs than they ought to be, though Mr. Corbet has raiſed immenſe crops there, worth twenty pounds an acre. In Cardiganſhire alone, of all the counties in the principality, it is ſaid that they are univerſally cultivated; making, with Barley bread, the chief ſuſtenance of the poor. A few years ago a large portion of what were uſed, was annually imported from Liverpool. Of late the quantity has been inconſiderable; and thoſe imported are brought chiefly for change of ſeed.

The Potato, ſays Dr. Anderſon, from Ireland paſſed over to Scotland; and the man has not been dead many years who firſt introduced the culture into the the peninſula of Cantire. He lived near Cambleton. From him the city of Glaſgow obtained a regular ſupply for many years, and from him alſo the natives of the Weſtern Highland and Iſles obtained the firſt plants, from which have been derived thoſe abundant ſupplies on which the people there now principally ſubſiſt. Being once known at Glaſgow, the culture ſoon ſpread abroad; but ſo lately were they introduced as a field crop in the eaſt of Scotland, that I myſelf remember the firſt field that was planted with Potatoes in that neighbourhood, which was only five miles from Edinburgh[k].

If we may judge from the late agricultural ſurveys, the culture of this root, on a large ſcale, has made a rapid progreſs. Dr. Smith, the reporter for the county of Argyll relates, that Potatoes have been long and

much

Digitized by Google

much cultivated there; moſt of the inhabitants living chiefly upon them for more than three fourths of the year. Dr. Thomſon, in his view of the agriculture of the county of Fife informs us, that about ſixty years ago, the Potato was chiefly to be ſeen in gardens; few were planted in the fields. It is only within the laſt twenty or thirty years that its value has been well underſtood, and the cultivation of it has become general. Potatoes were firſt cultivated in the fields of Mid-Lothian about the year 1744; they had not been long introduced, even into gardens, before that time. They are now (1795) in every farm; but few are raiſed for ſale above ſix miles from Edinburgh, or other towns; the expenſe attending their carriage being too great to admit of bringing them from a farther diſtance. There may be from twelve hundred to fifteen hundred acres cultivated.

The culture of Potatoes is carried to a great extent in the county of Perth, eſpecially in the Highlands.

Potatoes, ſays the Rev. Dr. Robert Douglas in his general view of Roxburgh and Selkirk (1798), about forty years ago, were not raiſed in the fields, except on narrow beds, in deep marſhy ſpots. And a gentleman, now dead, remembered, that ſome years before 1745, he was admitted as a great favour into a garden to ſee Potatoes growing.

So little was the attention paid to the improvement of this plant, that Mr. Miller, in his laſt folio edition of his Dictionary in 1768, and his laſt quarto edition of 1771, makes no mention of any varieties, except thoſe which occur in all the old authors: namely, one with a red root, and another with a white root.

To enumerate all the varieties which have been raiſed from ſeed, would be uſeleſs, becauſe they are continually paſſing away, and giving place to others that have more favour, if not more merit, for a time. But the following are known at preſent in different parts of the country.

Apple; one of the Kidney ſort. Ireland and the Iſle of Man.

Black or Blackmoor. Fit for cattle and the table. A late ſort, and keeps well till auguſt. It affords more ſtarch than ſome others, and is of greater ſpecific gravity. The outer coat is ſooty, but when rubbed it appears of a dark or bright purple. It will grow in a heavy moiſt ſoil.

Brown, Early.

Champion. For cattle and the table. In 1784 it was preferred in Eſſex, becauſe it did not curl. Comes early. Called alſo Globe-white.

Cluſter or conglomerate, called alſo Suffolk or Howard: called Hog Potato in Kent. Red and ſtreaked with red within. Taſte ſaccharine.

Cluſter, White. Yellowiſh within, white on the outſide. Conglomerate like the red.

Commonwiſe. Iriſh.

Copperplate: hardy and ſtrong. Iſle of Man.

Cornwallis. Suffolk.

Crones. Iriſh.

Cumberland Early. Large, prolific, well flavoured; ripens early enough to admit of another crop.

Dun, Golden and Long, Iriſh.

Dutch upright.

Goldendabs. Yellow and kidney-like, ſomewhat bell-ſhaped.

Golden-dun. See Dun.

Goldfinders. Yellow within, kidney-like, with a ſcurfy rind, not unlike the old Ruſſet. A good ſort, cultivated in the midland counties.

Goldentags.

Henley, Early. Round, not deeply indented at the eyes, dirty white, ſkin ſmooth and fine but not ſilky, ſeldom exceeding a large hen's egg in ſize.

Horſe-legs. Somerſetſhire.

Hog. See Surinam.

Iriſh Blue.

Kentiſh. Seedling. Very large and white [1]. Other varieties raiſed from ſeed have the names of the perſons who firſt raiſed them. As Bayley's ſeedling; middle-ſized, white and mealy; exceeding well-flavoured.

Kidney. There is a great variety of Kidnies, both white and red: as the Lincolnſhire. Red-noſe, large and ſmall; neglected in Eſſex ſo long ſince as 1784, on account of its being ſubject to the curl [m]. True. White. Flat White, called by ſome the true Spaniſh. Superfine White; ſaid to be the earlieſt Potato in Lancaſhire, where they ſometimes raiſe four crops in a year of this variety on the ſame ground. For other Kidnies ſee White and Red, and Manley.

Killamancas: in Lothian.

Magpye.

Manley, White. Large, white, mealy and well-taſted.

Ox-noble; for cattle. Large, prolific, apt to be hollow. Called in ſome places white Surinam, and confounded with the White Cluſter, from which however it differs. See Surinam.

Peach.

Pheaſant-eye.

Pink-eye or Redſtreak, hardy and ſtrong; late and beſt for eating in the ſpring; in uſe till the beginning of july. Pink-noſe the ſame probably with Red-noſe Kidney.

Pomgranate. Dark purple. Hard, ſolid and heavy. Keeps well, and is good for cattle. Probably the ſame with the Black.

Quakerwiſe. Iriſh.

Red. Blood Red. Iriſh Red, or painted Lord: late, plentiful. Old winter Red: peculiarly good in ſpring, when others have loſt their flavour; it never has the curl. Rough Red. Purple. Red French; Iriſh. Red-ſnout or Red-nob; large, prolific and well-flavoured; but becomes ſtrong-taſted in ſpring [n]. For other varieties ſee Kidney.

Royal. See Cumberland early.

Ruſſet, white and red: for winter uſe.

Scotch, white and gray.

Silverſkin.

Spaniſh. See Kidney.

Surinam or Hog Potato, called in ſome places the cluſter, and confounded with the true Cluſter. Very prolific and adapted to the uſe of ſtock. White and Red. The White of ſome places ſeems to be the ſame with the Ox-noble. The Cluſter, Ox-noble and Surinam are all called Hog Potatoes in different counties, and are uſed indifferently for feeding cattle and hogs. Cow Potato of Staffordſhire the ſame with the Red Surinam.

Tartar. Pale red ſtreaked with white, eſpecially at the top end; round and hollow-eyed.

Tawny.

White. Ayleſbury, called alſo Winter white and white bloſſom; good for the table, larger and producing a more bulky crop than the Champion. Engliſh White; Iriſh. French White; Iriſh. Lady White. Long White. Manley White. Munſter White; Iriſh. Oblong flat White. Round White. Rough White. Scotch White. See Cluſter, Kidney, Manley, Ox-noble, and Surinam.

Yam. A coarſe Potato, raiſed principally for horſes, prolific and growing on indifferent land [o]. It is a bad name becauſe it makes a confuſion with the Weſt Indian Yam properly ſo called. Dioſcorea ſativa.

Several of the above varieties are probably the ſame under different names: and ſome which are different have the ſame name in different diſtricts. Such as they are they form a liſt of the Potatoes now or lately in cultivation. The deſire of improvement and the thirſt for gain are daily prompting men to raiſe new varieties, eſpecially about Mancheſter and Liverpool; and if old varieties be wearing out, it is the more neceſſary to raiſe new ones from ſeed.

This Virginian Potato, when firſt known in Europe, was endued with all the fancied properties of the

[1] Kent's view of Norfolk, app. 195. 8vo. edit. Bath papers, 4. 298.

[m] Marſhall's midl. 1. 248. [n] Agric. view of Roxb. [o] Idem.

Spaniſh;

Digitized by Google

Spaniſh; but on the contrary was reprobated by ſome as cauſing the leproſy. The preſent age is contented to reſpect this root as a wholeſome and nutritious food. The farinaceous varieties make a good ſtarch, and bread either mixed with wheat flour or even alone. But all the varieties are beſt eaten plain boiled or baked, whether applied to our own uſe or that of our domeſtic animals.

32. Habit, ſtature, &c. of S. Lycoperſicum. Fruit like that of its variety β. But it differs altogether from S. Lycoperſicum in having the ſtem ſmooth without any hairs ſcattered over that or the peduncles, the leaves ſmooth entire cordate not at all gaſhed or toothed as in that. However as it agrees upon the whole in ſtructure, it may perhaps come from that. The ſtructure of the peduncles is the ſame as in tuberoſum, Lycoperſicum and peruvianum, with the pedicels alſo jointed, and the raceme naked, as in the two former, not leafy as in the laſt [p].—Native of Peru.]

Mr. Miller ſays it is ſomewhat like the Lycoperſicum, but that the leaves have ſome ſmaller leaflets between the large ones, and have not that rank diſagreeable odour which the other has; that the leaflets are ſhorter, broader, and not cut, having only ſome obtuſe indentures towards the baſe; that the fruit is not ſo large, but round and ſmooth, and late before it ripens.

33. This is an annual plant, with an herbaceous, branching, hairy ſtalk, riſing to the height of ſix or eight feet, if ſupported, otherwiſe the branches will fall to the ground. Leaves pinnate, of a very rank diſagreeable odour, compoſed of four or five pairs of leaflets terminated by an odd one, cut on their edges, and ending in acute points. Flowers axillary on pretty long peduncles, each ſuſtaining ſeveral yellow flowers, forming a ſingle long bunch.

[The fruit is ſmooth, but varies in form, ſize and colour; which has given occaſion to Miller to make two ſpecies.] The one commonly cultivated in the South of Europe to put into ſoups and ſauces, to which it imparts an agreeable acid flavour. The fruit in this is very large, compreſſed both at top and bottom, and deeply furrowed all over the ſides, red or yellow.

β. The other round, about the ſize of a large Cherry, either yellow or red. [Loureiro deſcribes the berry in Cochinchina as white, middle-ſized, roundiſh, three-lobed and ſmooth.

Native of South America. Cultivated in 1596 by Gerarde. It flowers from july to ſeptember [q],] or till ſtopped by the froſt, and the fruit ripens from the end of july, till autumnal froſts come on.

[34. Leaflets wrinkled, hairy, toothed and gaſhed, unequal [r]. Berry not grooved, leſs than in the preceding, yellow [s].—Native of St. Helena. Annual.

35. Root perennial; ſtem ſcarcely or very little ſhrubby above the root. Leaves hoary, pinnate without any ſmall leaflets between the larger ones. Racemes two-parted with an ovate leaflet to each pedicel. Corollas bright yellow, much bigger than in S. Lycoperſicum [t].—Native of Peru.

According to Loureiro it is wild in the gardens of Cochinchina; the flowers are of a gold colour, and the berry is ſaffron-coloured, hairy, ſmall, roundiſh, compreſſed, three-celled, many-ſeeded and eſculent.]

Miller ſays it is annual, and has a very branching herbaceous ſtalk, ſpreading out into many diviſions, and not ſo hairy as S. Lycoperſicum; the leaves have a greater number of leaflets, which are much ſhorter and more indented on their edges, where they are a little waved, and are downy. The flowers ſtand upon very long peduncles, which branch out and ſupport a great number of flowers at the top; the ſtyle is longer than in the other ſpecies, and remains on the top of the fruit, which is late in ripening. The ſeeds of this and of n. 32. were ſent from Peru by Monſ. Joſ. de Juſſieu to the royal garden at Paris; and were imparted to Miller by his brother Dr. Bernard de Juſſieu.

[p] Linn. amoen. [q] Hort. kew. [r] Jacquin. [s] Willdenow. [t] Linn. ſpec.

36. Native of Peru.

37. Native of the iſland of St. Helena.

38. This is an unarmed upright ſhrub, ten feet high, ſmooth, weak; branches round, ſubdichotomous, erect, knobbed at the diviſions. Leaves alternate, petioled, ovate, acute, quite entire, thin, green on both ſides, veined, decurrent more or leſs along the petiole, the longeſt half a foot in length. Common peduncles filiform, an inch and half long, patulous, round, green, umbelled, lateral from the knots of the branches below the leaves. Proper pedicels about ſix, one-flowered, filiform, a third of an inch in length. Flowers ſmall. Calyx minute, green; leaflets oblong, obtuſe, flat. Petal white, yellow at the baſe, deeply five-cleft, ſegments lanceolate, acute, ſpreading very much. Berry globular, the ſize of a ſmall pea, dark-coloured, ſmooth and ſhining. Seeds whitiſh. It is called Bret by the Malays, who cultivate it as a pot-herb [u].—Native of the iſland of Mauritius.

39. Root annual, much branched. Stem branched, ſpreading, leafy, angular, ſometimes winged, and often of a woody hardneſs, ſurviving the winter in our mildeſt ſeaſons as in hot climates. Leaves alternate, petioled, ovate, repand, lengthened out at the baſe, ſomewhat downy. Umbels lateral, from the interſtices of the ſtem between the leaves, nodding, downy, bearing a few white flowers, ſmelling like muſk. Berries globular, black when ripe; ſometimes yellow [x].] Miller ſays there are two varieties of the common Nightſhade growing naturally in England. The moſt common, an upright branching plant, with oval acute-pointed ſmooth leaves, and black berries: the other, a low branching plant with indented leaves, and greeniſh-yellow berries. [The latter has laciniated leaves, according to Gærtner; who deſcribes the berry as globular, ſubvilloſe, yellowiſh, ſubdiaphanous, two-celled, having a membranaceous partition, connate with the receptacle, which is fleſhy and ſolid, growing cloſe to the middle of the partition. Seeds about twenty-five in each cell, ovate-acuminate, beaked, compreſſed, girt with a membranaceous rim, and wrapped up in a ſoft yellowiſh tranſparent pulp.

This ſpecies is common in Europe, Africa and America, both in cultivated and waſte ground, eſpecially on dunghills; flowering from june to ſeptember. It varies in ſize, as well as in the hairineſs of its leaves; but may be known at firſt ſight, when in perfection, by the bunches of flowers or fruits hanging from the ſpaces between the joints of the ſtem and branches [y].

There is little doubt of the herb and berries being both poiſonous, though ſome perſons have eaten them without any bad effects following.

The whole herb is fetid, narcotic, and promotes perſpiration and urine. From one to three grains of the dried leaves infuſed in boiling water, and taken at bed-time, occaſions a copious perſpiration, increaſes the ſecretion by the kidnies, and generally purges more or leſs the following day. Theſe properties, judiciouſly applied, render it capable of doing eſſential ſervice in ſeveral diſeaſes, as inveterate ulcers, ſcrophula, &c. and even in dropſies; as may be ſeen in Mr. Gataker's treatiſe on the Solanum publiſhed in 1757. Too large a quantity occaſions violent ſickneſs, with head-ach, giddineſs, drowſineſs, and other dangerous ſymptoms. In ſhort, its effects on the nervous ſyſtem are ſo uncertain, and ſometimes ſo conſiderable, that it muſt ever be adminiſtered with the greateſt caution. Mr. Bromfield, an eminent ſurgeon, ſo far from approving of the Solanum, declares that the caſes in which he tried it were much aggravated by it; and his opinion has prevailed ſo far, that it ſeems now to be little uſed. This is perhaps to be lamented, ſince it might probably be of ſervice in diſeaſes, where the medical practitioner could otherwiſe do little more than ſympathize with his diſtreſſed patients.

The leaves, applied externally, abate inflammation and aſſuage pain. With the Arabians it is a common application to burns and ulcers; and if it be

[u] Jacqu. collect. [x] Smith. [y] Engl. bot. & Curt. lond.

Digitized by Google

the Στρυχνος κυνταιος of Dioſcorides, it was uſed anciently as a diſcutient and anodyne in various affections of the ſkin, tumefactions of the glands, ulcers, and diſorders of the eyes. As a ridiculous application of this plant it may be mentioned, that an ointment made of the leaves with hog's lard was uſed by Solano de Luque, a famous Spaniſh phyſician, about two centuries ſince, in the cure of conſumptions. The patient was to be buried for ſome time up to the chin in the earth, and afterwards rubbed with this ointment [a].—The genuine properties of this plant, Solanum Dulcamara or woody Nightſhade, and Atropa Belladonna or deadly Nightſhade, ſeem to be nearly the ſame.

Beſides the varieties of the common Nightſhade already mentioned there are others ſo conſiderable as to have induced Mr. Miller to make ſeveral diſtinct ſpecies; and Dr. Withering, to ſuſpect that Linneus had confounded different ſpecies under the name of Solanum nigrum, till he was convinced of the contrary by the judicious remarks of the Abbé Correa de Serra. In Portugal and other warm climates the ſtem is woody, and the plant is biennial if not perennial.]

Mr. Miller is of opinion that our common Nightſhade, although it is now become a very troubleſome weed in many gardens near London, yet is not a native of this country, but was brought originally from America, whence the greater part of the ſpecies have been introduced into Europe.

[Dillenius has deſcribed and figured ſeveral varieties: as

β. Which is three cubits and more in height, with a ſtout ſtem as thick as the human thumb at bottom, green, round and ſmooth, ſtriated and as it were angular, branching from a foot or two feet from the bottom to the top, and theſe ſubdividing. Leaves ſmooth, entire, like thoſe of the Guinea variety, only in that the ſtem-leaves are much larger. It is an annual plant, although ſo ſtout and lofty. It is diſtinguiſhed from the common ſort by the branches ſpreading, and extending themſelves very wide. It ſeems to be the Aguara-quiya of Marcgraaf.

γ. The whole plant is covered with ſoft hairs, the ends of the branches eſpecially are lanuginoſe with long hairs, through which the purple colour of the branches ſhines; nay the flowers themſelves are woolly on the outſide and at the edges. The plant is larger and ſtouter, and the flowers are ſomewhat bigger than in the common ſort. The ſtems are ſometimes upright, but are commonly lower with the branches reclining. Berries duſky green, when ripe ſaffron-coloured, not round but oblong. The leaves are duſky green above, but paler beneath. Bobart and Ray had it from Morgan. The native place was unknown to them. If it be the ſame with the ægyptiacum of Forſkahl, it is indigenous of Egypt.]

Mr. Miller has two ſpecies which ſeem to be the ſame with this variety. S. villoſum, n. 2.—S. offic. acinis puniceis. *Bauh. pin.* 166. and ſecondly, S. luteum, n. 3.—S. offic. acinis luteis. *Bauh. pin.* 166.—The former riſes with an erect branching ſtalk three feet high. Leaves oval, angular, indented and ſmooth. Flowers white. Berries yellow. Seeds from Barbadoes.—The latter riſes with hairy branching ſtalks two feet and a half high. Leaves woolly, oval, ſpear-ſhaped, acute-pointed, indented on the edges. Flowers like thoſe of the preceding. Berries of the ſame ſize and ſhape, but of a red colour. Seeds from America.

δ. This riſes with a ſtrong thick herbaceous angular ſtalk two feet and a half high, dividing into ſhort thick branches. Leaves oblong, oval, ſmooth, near five inches long, and three and a half broad, having a few indentures, and ſtanding upon pretty long foot-ſtalks. Flowers larger than in the common ſort. Berries the ſize of the common black Cherry.—Native of Guinea.

[Dillenius remarks, that there are blunt ſpines here and there at the angles of the ſtem, which is upright and not branched; that the leaves reſemble thoſe of Atropa Belladonna, and are ſmooth except that they have a few ſlender hairs on the upper ſurface, deep green above, paler beneath; thoſe on the middle of the ſtem much bigger than the branch-leaves. Flowers ſmall, white or ſometimes ſlightly tinged with violet, greeniſh at the claws. Anthers duſky or browniſh. Berries globular, almoſt as large as black Cherries, but more depreſſed, green at firſt, but black and ſhining when ripe. Seeds whitiſh, compreſſed, lying in a violet-coloured pulp. It is an annual plant.

ε. This differs from variety β. in not riſing ſo high, and in being leſs branched and ſpreading; the upper leaves are ſinuated, the middle and lower laciniated, and not unfrequently divided as in Lycopus or water Horehound; the flowers are ſomewhat bigger, and more of a violet colour; the ſtems are more angular, and roughened or ſpiny at the angles. The leaves are deep green, and the lower ones not unlike thoſe of Stramonium or Thorn-apple. The flowers become paler and at length white. The berries are round, at firſt green, but black when ripe. It is an annual plant, native of Virginia [a].

Swartz remarks that the prickles at the angles are very ſmall and recurved. According to him it is the ſixth Solanum or branched Caleloo of Browne, who ſays that it is very common in the low lands of Jamaica, ſeldom riſing more than two or three feet from the root; that it has none of the viroſe ſmell and narcotic quality of the European Nightſhade, and is daily uſed for food, being found a pleaſant and wholeſome green; that the only difference between the two plants is the length of the common foot-ſtalks, and the length and ſmoothneſs of the branches, except that the European ſeems to grow more twiggy and luxuriant.]

Miller ſays, the ſtalks riſe three feet high, and divide into ſpreading branches; they are angular, furrowed, and have a few ſhort ſpines; the leaves are oval and entire, ſix inches long and five broad, dark green and on long foot-ſtalks; flowers ſmall, white; berries ſmall and black.

The americanum, n. 5. is probably not different from this: the ſtalks are angular, upwards of three feet high, and divide into a few ſlender ſpreading branches; leaves oval, acute-pointed, ſmooth, deep green, having a few indentures on their edges; flowers few in each umbel, ſmall, white on the inſide, and purpliſh without; berries ſmall and black.

[ζ. This is ſuppoſed to be a mere variety of the preceding.]

η. This has taller and ſmoother ſtalks than the preceding; leaves dark-green, ſmooth, oval, acute-pointed, angularly indented on the edges; flowers in nodding lateral umbels; berries ſmooth and red. The ſeeds came from the Weſt Indies.

[ϑ. Fruit black. Native of Egypt [b].

Linneus regards theſe varieties as hybridous offſprings or mules; Willdenow thinks that they may be diſtinct ſpecies, ſince they are not altered by culture.

40. Root annual. Stem ſtiffiſh. Leaves like thoſe of S. bonarienſe (n. 29.), a hand in length, blunt. Fruit red, large, depreſſed, ſo deeply furrowed as to be in a manner cut into lobes, hard [c].

Branches diffuſed. Leaves ovate-oblong, ſinuate-repand. Flowers ſolitary, violet. Calyx and corolla ſix-cleft. Stamens ſix. Berry ſpheroidal, ſix-lobed, large, ſmooth, white or purple [d]. Jacquin obſerved prickles on the ſtem, ribs of the leaves, and calyxes.]

Stem erect, a foot and half high, dividing into ſeveral branches. Leaves oval, angular, from three to four inches long, and almoſt three inches broad in the middle, placed alternately on pretty long foot-ſtalks, which have one or two ſhort ſpines upon them, as there is alſo upon the midrib of the leaves. The flowers come out ſingly upon peduncles from the ſide of the branches; they are white, and are ſucceeded by red ſtriated fruit, firmer than thoſe of the other ſorts, and about the ſize of cherries.

[a] Withering, Engl. bot. Curtis, Woodville.

[a] Dill. elth. [b] Forſk. [c] Linn. ſpec. [d] Loureiro.

Digitized by Google

[Native of China, Cochinchina and Japan, where it is cultivated for the table.—It was cultivated here before 1597 by Gerarde[e]: who ſays the ſeeds were brought unto us out of Spain, and that his plants periſhed at the firſt approach of winter. He, with other old authors, derived its original from Ethiopia, and Linnæus continued the miſtake in his trivial name.

41. Stem annual, thick, twiſted, two feet high, with the branches reclining. Leaves ovate, ſinuate, large, few, ſcattered, on thick petioles. Flowers pale violet; pedunçles axillary, thickened, bent down, one-flowered, moſt commonly ſolitary, but not unfrequently two or three together. Berry large, ſhining, two-celled, many-ſeeded, eſculent. Varieties of it are, 1. With an oblong violet-coloured fruit. 2. With an oblong white large fruit. 3. With a globular violet-coloured fruit. 4. With a globular white or variegated fruit[f].]

Mr. Miller has four ſpecies of Melongena, the three firſt of which are unarmed, and differ in the ſhape of the fruit; the fourth is prickly.

They are all annual plants, with an herbaceous ſtem, becoming a little woody, riſing near three feet high, and ſending out many ſide branches. Leaves in the firſt and ſecond oblong-ovate, ſeven or eight inches long and four broad, woolly, ſlightly ſinuated but not indented on their borders, ſtanding without order upon very thick foot-ſtalks: in the third the leaves are more deeply ſinuated. The flowers come out ſingly from the ſide of the branches. The calyx is armed with ſtrong prickles on the outſide. Corolla blue. In the firſt the fruit is ovate, about the ſize of a ſwan's egg, of a dark purple on one ſide, and white on the other: ſometimes it is white, whence this ſpecies is called the Egg-plant; or yellow, or pale red. In the ſecond, the fruit is commonly eight or nine inches long, taper and ſtraight; purpliſh or white. In the third, it is oblong and incurved, yellowiſh, and largeſt at the end. The fourth differs greatly from the others; the ſtalk and leaves being armed with very ſtrong thorns; the leaves larger, and deeply jagged on their ſides; the flowers larger, and of a deeper blue colour; the fruit long, taper and white. The ſeeds were ſent from India.

The fruit of the firſt of theſe is commonly eaten by the inhabitants of Aſia, Africa and America. It is cultivated in the gardens of Spain by the title of *Barenkeena*; the Turks, who alſo eat it, call it *Badinjan*; the Italians *Melanzana* (Mala inſana), and the inhabitants of the Britiſh iſlands in the Weſt Indies, *Brown John* or *Brown Jolly*.

[But the Brown Jolly or Bolangena of Jamaica, is, according to Browne, a rough prickly ſort. The plant, he ſays, lives ſome years, and ſeldom riſes above three or four feet in height. It was firſt introduced by the Jews, and bears a number of large berries, which being ſliced, pickled for a few hours, and then boiled to tenderneſs, are uſed inſtead of greens.

In the Eaſt Indies, the fruit is broiled, and being peppered and ſalted, is reckoned very delicious. But it is remarked by Dr. Ruſſel, that though Melongena is cultivated in the Levant for eating, it is the inſanum which they grow in the Eaſt Indies for that purpoſe.

Loureiro however inſiſts, that the inſanum of Linneus is not ſpecifically diſtinct from Melongena; having obſerved prickles on the latter from the ſame ſeed with the ſmooth ones, and in the ſame garden. The plants appear to be moſtly unarmed, but ſome are prickly, either on the calyx, the leaves, ſtem or branches. Rumphius had made the ſame obſervation before.

The Egg-plant is a native of Aſia, Africa and America, where the climate is warm enough. It was cultivated before 1597 by Gerarde[g]: under the name of Mala inſana, mad or raging Apples. It muſt be ſown in April, ſays he, in a bed of horſe-dung, as Muſkemelons are. It grows in Egypt almoſt every where; and bore fruit of the bigneſs of a gooſe egg one extraordinary temperate year, in the garden of a worſhipful merchant, Mr. Harvy, in Lime-ſtreet.

[e] Hort. kew. [f] Loureiro. [g] Hort. kew.

42. This is a ſhrub from four to ſix feet high, with a round branching ſmoothiſh ſtem, covered with a mealy down, eſpecially the branches. Leaves petioled, alternate, ovate or oblong, acuminate at both ends, three or four inches long, ſmooth above, more or leſs tomentoſe beneath. Racemes an inch long, lateral, many-flowered: pedunçles cluſtered, cymed, one-flowered. Flowers biggiſh, blue: ſegments of the calyx blunt; of the corolla ſpreading and lanceolate. Berries globular[h].]

Stem ſhrubby, ſmooth, ſix or ſeven feet high, ſending out woody branches on every ſide, which have a ſmooth brown bark. Leaves ovate, acute-pointed, entire, woolly on their under ſide, four inches long, and two inches and a half broad. Flowers collected into umbels which ſtand erect, and come out from the ſide or at the end of the branches: they are of a light blue colour, and are ſucceeded by round berries, the ſize of ſmall black cherries, which are yellow when ripe.

[Native of the Weſt Indies. Diſcovered by Houſtoun at Campeachy, and by Jacquin at Carthagena.—Introduced in 1778 by Mr. Gilbert Alexander[i]: but cultivated by Miller before 1733.

43. This is a ſhrub, with round branches, ſmooth below, but of a dirty aſh-colour above with minute ſtellate villoſe hairs. Leaves alternate, remote, three or four inches long, obtuſe and almoſt equal at the baſe, attenuated at the tip, ſomewhat rugged on the upper ſurface with ſtellate hairs viſible only with a magnifier; the older leaves almoſt ſmooth, obſcurely veined: underneath more villoſe with a dirty nap, eſpecially the younger ones. Petioles half an inch long, hoary. Peduncles lateral towards the top, the firſt ſhort and recurved, then gradually longer and ſtraighter. Pedicels alternate, eight to ten, half an inch long. Calyx tomentoſe-hoary; with five awl-ſhaped teeth, four times as ſhort as the corolla; which is almoſt an inch wide, and deeply five-cleft: ſegments linear-lanceolate, attenuated, obtuſe, tomentoſe without, ſmooth within.—Found at Cayenne by von Rohr[k].

Vahl ſeems to think this ſcarcely different from the preceding, yet it appears to be diſtinct in the inflorescence, calyx and corolla[l].

44. Native of Peru. Introduced in 1785, by Monſ. Thouin[m].

45. Annual. Very nearly allied to S. Melongena. Stem ſcarcely branched, with a ſtellate nap on it. Leaves ſubſinuate. Peduncles ſolitary, one-flowered, pendulous, thickened. Fruit large.—It differs from that in having prickles ſcattered over the ſtem, a few ſtraight prickles on both ſides of the leaves, and the calyx very prickly[n]. Notwithſtanding theſe differences, Loureiro thinks they are the ſame ſpecies. See n. 41.

This is the ſort which is cultivated in the Eaſt Indies for eating. One much-eſteemed variety in ſome provinces is called *Mandia*. The flower is ſmall, of a duſky purple colour: the fruit is yellow, roundiſh, the ſize of an Orange; the leaves and calyx prickly.

It has been introduced into the Weſt Indies for culinary purpoſes, ſays Swartz. The peduncles are ſhort, one-flowered, prickly, incraſſated: the corollas blue, large, and nodding; the fruit the ſize of a gooſe's egg, ovate, very ſmooth, yellow white or blue. It varies in the gardens, with an unarmed ſtem, and rugged-hirſute leaves hoary with meal behind.

46. This is a ſhrub, a fathom in height, with round tomentoſe prickly branches. Prickles awl-ſhaped, wider at the baſe, a little bent back, and as it were tomentoſe. Leaves alternate, often two from one point, cordate-ovate, acute, ſinuate-angular, with the ſinuſes angular and the lobes ſharpiſh, tomentoſe with very ſhort ſtellate green hairs, and beneath with longer whitiſh ones, prickly along the rachis. Prickles ſcattered, diſtant, from a wider baſe, compreſſed, awl-ſhaped. Petioles round, tomentoſe, defended beneath with ſtraight ſcattered prickles. Racemes lateral, compound, panicle-form, peduncled, with the flowers

[h] Swartz. [i] Hort. kew. [k] Vahl.
[l] Willdenow. [m] Hort. kew. [n] Linn. mant.

pedicelled,

Digitized by Google

pedicelled; cymed. Peduncles and pedicels round, unarmed, tomentoſe. Calyx bell-ſhaped, unarmed, ſubvilloſe, ſcarcely three lines in length; ſegments ovate, acuminate. Corolla white; border an inch in diameter. It varies with unarmed leaves, the petioles only having here and there prickles on them. It reſembles S. indicum very much; but differs in having the leaves quite unarmed above, and the rachis only prickly underneath; the racemes more branching; and the calyxes unarmed.

Native of Jamaica, Hiſpaniola, and the Bermuda iſlands, in hedges.

47. Stem ſhrubby, climbing, branched, round, prickly. Leaves three or four inches or a ſpan long, lanceolate-ovate, toothletted at the edge, rough above, beneath hiſpid with ferruginous hairs, nerved not rigid. Petioles flatted a little, prickly backwards; as is alſo the midrib: prickles ſmall, recurved. Racemes lateral, alternate with the petioles, ſhorter than the leaves, ſimple, many-flowered, looſe: pedicels half an inch long, alternate, approximating, one-flowered. Calyx five-cornered, five-toothed, ferruginous-pubeſcent, prickly, reflexed. Corolla larger, blue; ſegments long, tomentoſe beneath. Filaments ſcarcely any: anthers length of the corolla, erect, contiguous, thicker below, alternating at top, perforated by two pores. Berry placed on the permanent calyx, umbilicate [o].

Vahl conjectures that his *ſcabrum* is allied to this; and Willdenow unites them with a mark of doubt.—Vahl thus deſcribes his *ſcabrum*. It is a ſhrub, with round flexuoſe branches, ſomewhat rugged with obſcure ſtellate hairs, armed with recurved compreſſed yellow ſmooth ſhort prickles. Leaves three together on the ſame ſide of the branch, one four or five inches long, the ſecond three inches, and the third ſometimes ſcarcely an inch in length; the larger two inches wide, elliptic, acute at the baſe, bluntiſh at the tip, ſubſinuate with two or three angles on each ſide, ſtellate-hairy and rugged on both ſurfaces, paler beneath on account of the ſtars of hairs being cloſer; the midrib prickly on both ſides: ſmall prickles on the face of the branches. Rudiment of a branchlet in the axils, with leaves tomentoſe of a dirty yellow colour. Petiole half an inch or an inch long, prickly. Racemes lateral, ſolitary, two inches long, when the lower flowers are paſt, bent back. Pedicels half an inch long, filiform, ſometimes armed with a needle-like prickle, when fruit-bearing curved upwards, covered with ſtellate hairs, as are alſo the peduncle and calyxes. Calyx ſhort, prickly; prickles frequent, needle-like: ſegments lanceolate, acuminate. Segments of the corolla linear, tomentoſe-hoary on the outſide. Berries ſmall, ſmooth.

Found in the woods of Hiſpaniola by Swartz; and in the Weſt Indies by von Rohr.

48. Stature of S. Melongena. Leaves wide, petioled, having upright prickles on the veins, villoſe above, tomentoſe beneath. Petioles, peduncles and calyxes prickly. Peduncles axillary, ſimple, ſhort. Calyxes bell-ſhaped, tomentoſe, armed with ſtout prickles, covering the whole berry. Berries very rough-haired.—Native of Malabar [p].

49. This reſembles the *virginianum* (n. 55.) in its leaves and manner of growth, but the whole plant is hairy, the flowers paler and a little ſmaller, the fruit bigger and not variegated, but white when ripe. It grows from a foot to two feet in height, with the branches ſcattered on every ſide, from round angular, duſky purple towards the ſun, armed with frequent browniſh or whitiſh prickles. Leaves large, variouſly laciniated, covered all over with ſoft hairs, whitiſh green underneath with more prickles, which are whitiſh or yellowiſh. Two or three flowers come out together on a common peduncle, each on a ſlender pedicel, of a middling ſize, pale purple, in a very prickly calyx. Berries large, at firſt green, then white and ſhining. Some of the flowers are male, others female; the latter appear firſt, and have more prickly calyxes; both are on the ſame common peduncle, and have all the parts; but in the former the ſtyle and germ are abortive, and in the latter, the anthers have no pollen. It is not unuſual with ſome of the other ſpecies to have barren flowers. The whole plant is prickly, and beſides this, the branches, petioles and peduncles are covered with a thick nap. It is an annual plant, and roſe from ſeed ſent by Houſtoun from Campeachy [q].

According to Swartz, this is the *acanthifolium* of Miller, who ſays that] it was diſcovered by Houſtoun at La Vera Cruz in New Spain, whence he ſent the ſeeds to England, which ſucceeded in the Chelſea garden.—It riſes with a prickly herbaceous ſtalk near two feet high, dividing into two or three branches, cloſely armed with ſlender yellow ſpines of unequal lengths. Leaves ſix inches long, and three inches and a half broad, bright green and deeply ſinuated; the veins armed with yellow erect ſpines on both ſides. Flowers very large, of a fine blue colour. Berries round, as large as common cherries, marbled with white and green. Calyx armed with ſpines like a hedgehog. It flowers in july and auguſt, and the fruit ripens late in the autumn.

50. Annual. Branches variouſly ſpiny, browniſh on the ſide next the ſun. Leaves repand, ſinuate, obtuſe, green on both ſides, with ſpines on the upper ſurface of a bright purple colour, frequently girt with a pale band. The peduncles have ſtouter ſpines on them. Flowers violet-coloured [r].

This is wrongly united with the preceding in Syſtema Vegetabilium and Mantiſſa. The deſcription of S. campechienſe in the Mantiſſa belongs to this ſpecies [s]: it is as follows.

Stem a foot high, becoming ſhrubby, round, hairy, prickly, annual as well as the root; prickles ſtraight, ſpreading, ſcattered, purple; hairs ſpreading, of the ſame length with the prickles. Leaves petioled, cordate, laterally five-lobed to the middle, the leaves obtuſe, the ſinuſes blunter, elevated, ſpreading: the larger veins on both ſides have a few ſtraight prickles on them: the midrib is white or purple. Petioles the length of the leaves, prickly and hairy, purple on their upper ſide, and having raiſed dots ſcattered over them. Peduncles lateral, prickly, two together, the one having one flower only, the other commonly four flowers. Corollas white or blue. Filaments the length of the anthers, white. Anthers yellow, with a paler yellow beak. In the flowers that firſt come out the calyx is more prickly, and the anthers have no pollen. Native of America.]

51. This riſes with a prickly herbaceous ſtalk three or four feet high; the ſpines are ſtrong and crooked; the leaves are large, angular, woolly, and armed with the like ſpines; the flowers are produced in bunches from the ſide of the ſtalks; they are of a pale blue colour, and are ſucceeded by yellow fruit, the ſhape and ſize of a Catharine Pear inverted. The plant is annual here. It grows common in all the Weſt-India iſlands, where it is called Batchelor's Pear. See Dillen. elth. 363.

[Linneus ſays Virginia and Barbadoes, and remarks that the leaves are equal in length and breadth, and bluntiſh.

According to Loureiro, it is wild in Cochinchina. He deſcribes the ſtem as annual, hard, thick, five feet high, erect, prickly, tomentoſe, branched; the leaves as very large, roundiſh, angular-lobed, often cordate, prickly on both ſides, cinereous-villoſe, ſcattered; the flowers as white, on lateral many-flowered peduncles; the calyx as very hairy but without prickles; the berry as middle-ſized, round, yellow, hiſpid. It cannot well be the ſame with Miller's.

52. Stem ſhrubby, tomentoſe above, prickly: prickles ſtraight, ſmall, needle-like, ſcattered. Leaves blunt, with one or three unequal blunt angles on each ſide, tomentoſe on both ſurfaces, ſoft, whiter beneath: prickles ſcattered on the nerves both above and below, half an inch in length, ſtouter than on the ſtem, ſmooth, ſtraight. Petioles an inch long, prickly. Peduncles above, leafy, ſeveral, aggregate, half an inch long, one-flowered, very hirſute. Segments of the calyx ovate, acute, very hirſute on the outſide, as is

[o] Swartz. [p] Linn. ſpec. [q] Dillenius. [r] Linn ſpec. [s] Willdenow.

alſo

Digitized by Google

alſo the corolla, but that is ſmooth within; it is twice as long as the calyx, and three of the ſegments are a little longer than the other two.—Found by von Rohr on the iſland of Trinidad [t].

53. Stem and petioles white-tomentoſe, with few ſtraight naked prickles. Leaves tomentoſe, wide, cordate, deeply angular, ſharpiſh, unarmed, ſmooth above. Panicle terminating, compound, tomentoſe, unarmed, as is alſo the calyx.—Native of Braſil [u].

54. Allied to S. campechienſe, but the leaves are covered with thin ſhining hairs preſſed cloſe, the lobes of the ſegments have more rarely one or two large teeth, the calyxes have the prickles thinly diſperſed, and the corolla is of a different figure.—Native of America [x].

55. This differs from S. ſodomeum in having angular branches, but it is alſo annual. Spines copious, ſnow-white. Fruits ſmall, variegated with green and white [y].]

Annual, ſhrubby, prickly, about three feet high, ſending out a few ſlender branches. Flowers large, blue, with prickly calyxes. Berries almoſt the ſize of black Cherries.

[According to Dillenius, it is a foot and half or two feet in height, with a ſtem as thick as a ſwan's quill, of a duſky red colour, bending down at the joints, and extending its branches ſideways; the leaves are on long prickly petioles, in ſhape they are like thoſe of Acanthus, but ſmaller, bright and deep green, ſmooth and ſomewhat ſhining on both ſides, marked with white veins, and having long white prickles on the nerves, and along the edges on the larger leaves. Flowers ſix or ſeven in a ſort of ſhort ſpike, ſtained with violet. Filaments very ſhort: anthers more ſeparate than in moſt of the ſpecies. Calyxes very prickly. Berries of an oblong ſpheroidal form.

Native of America. Cultivated in 1656 by Tradeſcant, in whoſe garden Ray ſaw it.

56. Sufficiently diſtinct from the preceding, in having ſmooth leaves, not ciliate or prickly at the edge, and the ſtem decumbent not erect. It varies with the ſegments of the leaves ſcarcely ſinuate.—Native of the Eaſt Indies. Annual.

57. This is very like the preceding, but yet is different: the prickles on the ſtem are fewer, the leaves and flowers larger, the ſegments of the leaves more acute, and the leaves and younger branches are covered with ſtellate hairs.—Native of the Cape of Good Hope. Annual [z].

58. Stem tomentoſe, hoary, as is the whole plant: prickles ſcattered, needle-like, yellow, ſmooth, ſtraight. Leaves remote, two inches long, blunt, ſhorter on one ſide of the baſe, having three or four wide rounded quite entire lobes on each ſide; they are veinleſs on the upper ſurface, and for the moſt part unarmed; ſimply veined beneath, with needle-like prickles on the midrib, ſeldom on the veins. Petiole an inch and half long, with prickles ſcattered all over it. Racemes commonly oppoſite to the leaves, almoſt upright, eight-flowered. Peduncle rigid, an inch and half long: pedicels half an inch in length, reflexed, unarmed, as is alſo the peduncle. Calyx tomentoſe, very prickly, permanent: the prickles on it are ſtouter than on the reſt of the plant. Berries globular, the ſize of a hazel nut.—Native of Arabia Felix [a].

59. Stem a fathom in height, branched, prickly: branches flexuoſe, round, tomentoſe, prickly. Leaves in pairs, alternate, on very ſhort petioles, wedged at the baſe, widening towards the upper part, angular (but the angles ſo blunt as to be ſometimes obliterated) ſharp at the top, entire at the edge, ſcarcely repand, nerved, tomentoſe and ſomewhat rugged on both ſides, whiter beneath, and the midrib or rachis there prickly. Prickles ſtout, ſhort, reflexed, pale. Racemes lateral, much ſhorter than the leaves, ſimple, many-flowered: flowers pedicelled, ſubcymed; pedicels length of the raceme, crowded in two rows, filiform, one-flowered, looſe, tomentoſe, prickly. Calyx minute, prickly. Corolla ſmall, pale blue or white; with the ſegments reflexed and tomentoſe without. Berry roundiſh, firſt green veined with black, but wholly black when ripe, ſmooth, having a dot at the top, ſize of a red Currant.

It differs from S. indicum in having the leaves more tomentoſe, and angular without ſinuſes; the pedicels numerous, the flowers ſmall, and eſpecially the prickles ſubrecurved. It very much reſembles S. tomentoſum, but the leaves in that are cordate, and the prickles ſtraight.—Native of Jamaica and Hiſpaniola, in waſte places [b].]

Miller has a ſpecies under this name; but it is doubtful whether it be the ſame. He ſays it riſes with a ſhrubby woolly ſtalk five or ſix feet high, armed with ſhort recurved thorns, and garniſhed with oval woolly leaves ſix inches long and four broad, angularly ſinuate, and having a very few ſhort crooked ſpines upon the midrib on the under ſide. The flowers are in ſmall umbels ſitting cloſe to the ſide of the branches; they are ſmall and yellow, and are ſucceeded by ſmall round berries of a ſaffron colour when ripe.

60. Stem ſhrubby, two or three feet high, ſending out ſeveral woody branches, armed with ſhort, ſtrong, yellowiſh ſpines; leaves an inch and half long, and an inch broad, woolly on both ſides, and angularly indented, armed with ſpines on both ſides along the midrib. The flowers come out in longiſh bunches from the ſide of the ſtalks, they are blue and like thoſe of S. ſodomæum. Berries round, of a gold colour, as large as cherries.

[Height a cubit or a cubit and half. Stem the thickneſs of a finger, with an aſh-coloured bark, and browniſh, ſhorter and fewer ſpines than on the leaves; on which they are more frequent along the midrib and principal veins, eſpecially on the upper ſurface, they are alſo of a pale green colour. The leaves are ſinuate, like the next ſpecies, but more deeply, they are wider alſo and blunter: the younger ones are tomentoſe and ſomewhat hoary, but afterwards become green, only paler underneath, thick, and covered cloſely with hairs which are ſo ſhort and thin that they are detected rather by the touch than the ſight. Flowers five or ſix on a long common peduncle, like thoſe of the next ſpecies, but of a deeper colour, and not ſo frequent on a ſpike of the ſame length; they are bigger than thoſe of Borago, curled towards the edges, of a purpliſh blue colour; calyx hirſute, with narrow reflexed ſegments. Peduncles ſometimes with, and ſometimes without ſpines. Fruit pear-ſhaped; the ſeeds being ſent from Barbadoes under the name of Batchelor's Pear [c].

If ſo, Miller's mammoſum is probably this ſpecies.

Gærtner deſcribes the berry as a little larger than that of Aſparagus, of a colour from orange tending to red: the cuticle papery but hardiſh: the pulp watery. Receptacle oblong, flattiſh, growing every where to the partition. Seeds about twenty, compreſſed, ovate-kidneyform, pale.

Loureiro alſo ſays that the berry is ſmall, roundiſh and ſaffron-coloured. Dillenius therefore is probably miſtaken as to the fruit. Perhaps he was miſled by Robert's figure, which was not drawn for this ſpecies.

Native of the Eaſt and Weſt Indies, and of Cochinchina.

61. Stem in a manner ſhrubby, but yet annual. Leaves rugged, ſcarcely tomentoſe, entire at the baſe, ſinuate with ſharpiſh angles, and ſpines on the midrib, not at the ſides. Racemes longer than the leaves, looſe, ſimple [d]. Berries round, the ſize of a large pea, yellow when ripe [e].

Native of Carolina. This and the preceding were cultivated by James Sherard, M. D. in 1732. They flower in july [f].

62. Stem erect, ſhrubby, villoſe, covered with very numerous awl-ſhaped prickles. The thicker prickles white, the more ſlender brown. Leaves bipinnatifid or double-ſinuate, with the lobes blunt and quite entire, villoſe, armed with prickles on both ſides. Petiole

Digitized by Google

villoſe, prickly. Cyme extrafoliaceous, few-flowered. Peduncles very villoſe, prickly. Calyx villoſe, prickly, bell-ſhaped, covering the berry. Corolla yellow. Anthers diſtant. Berry the ſize of a Cherry, villoſe and armed with prickles. It differs from S. Sodomeum, in having villoſe bipinnatifid leaves, yellow corollas, and berries covered by the calyx [e].]

63. This has a ſtrong thick ſhrubby ſtalk, which riſes from two to three feet high, ſending out many ſhort thick branches, cloſely armed with ſhort ſtrong yellow ſpines on every ſide; the leaves are about four inches long and two broad; they are cut almoſt to their midrib in obtuſe ſegments, which are oppoſite, regular, and formed like winged leaves; theſe ſegments have ſeveral obtuſe indentures on their edges; they are of a dark green colour, and armed with the ſame ſort of ſpines as thoſe on the ſtalks, on both ſides. The flowers come out in ſmall bunches on the ſide of the branches, they are blue, and larger than in the *tomentoſum* (n. 70;) appear in june and july, and are ſucceeded by round yellow berries, as large as Walnuts. It grows naturally at the Cape of Good Hope.

[It is remarked in Syſtema Vegetabilium that the leaves are naked on both ſides.—It was cultivated in 1731, by Mr. Miller [h].

64. This plant is rough with abundance of prickles. Native of the Cape of Good Hope, where it was found by Thunberg.

65. Stem ſhrubby, white tomentoſe, with ſlender ſtraight ſcattered prickles. Leaves cordate, repand, green above, with a wide white margin, white-tomentoſe beneath, with ſtraight prickles on both ſides. Flowers racemed, bell-ſhaped, plaited, tomentoſe, white, like thoſe of S. tuberoſum, or the common Potato. Calyxes unarmed; when fruit-bearing prickly. Native of Abyſſinia [i]: of Africa, found by James Bruce, Eſq. and introduced in 1775. It flowers moſt part of the ſummer [k].

66. Trunk arboreous, ſix feet high, the thickneſs of the thumb, round, aſh-coloured, rough to the touch by inviſible tubercles. Prickles very abundant on both ſurfaces of the leaves, petioles, ſtem and branches; on the ſtem moſtly recurved, the reſt ſtraight. Leaves wide and large, with the petiole a foot long, cordate, alternate, lobed, acute, villoſe and ſoft on both ſides; the lobes ſublanceolate and acute; the petioles round, rough and villoſe. Common peduncles ſhort, on the ſtem and branches ſpreading horizontally: many pedicels ſpringing from them circularly. Theſe and the calyxes are ſomewhat villoſe and unarmed. Segments of the calyx very ſmall and roundiſh. Corolla pale purple or whitiſh; ſegments lanceolate, long and ſpreading very much. Germ roundiſh, very hirſute [l].

Jacquin ſays that this plant came up from ſeed ſent from the Eaſt Indies, about the year 1776:—but it is a native of the Weſt Indies; and was introduced here in 1778, by Meſſ. Kennedy and Lee: it flowers from june to ſeptember [m].

67. Native of the Canary iſlands, where it was found by Mr. Francis Maſſon. It was introduced in 1779; and flowers here in march and april [n].

68. Stem tomentoſe, aſh-coloured, with thick ſtraight ſhort yelloviſh prickles, tomentoſe except at the end. Leaves ovate, ſhorter on one ſide of the baſe, tomentoſe, thick, blunt; the young ones pinnately ſinuate, whitiſh at the edge, having three prickles on the rib. Petioles prickly underneath. Peduncles from the ſide of the ſtem: the primary pedicel with the calyx ſpiny, the reſt male and unarmed. Corolla like that of Borage, purpliſh-blue.—Native of Paleſtine [o].

69. This is ſhrubby, two feet high, and branched. Trunk round, the thickneſs of a finger, ſmooth, woody and aſh-coloured at bottom, the reſt green. Branches ſpreading very much, the upper part covered with a mealy nap. Leaves ovate, acute, tomentoſe on both ſides, repand-angular or more entire, pale-green, waved, petioled, commonly more produced on one ſide of the baſe, when young having a violet-coloured meal on the edge and at the back. Peduncles tomentoſe, duſky-violet, racemed, a few others umbelled, and very few one-flowered. Calyx tomentoſe. Corolla wrinkled, pale blue; with a wide border divided to the middle into five, ſix or ten parts. Some flowers, as in many ſpecies of Solanum, are abortive. Fruit roundiſh, depreſſed, ſhining, indiſtinctly unequally or ſcarcely at all grooved, unarmed, pendulous, orange-coloured with a thick coriaceous rind, moſtly without ſeed. Prickles ſmooth, ſtout, ſtraight or recurved on the ſtem and branches, but few; fewer or none on the midrib and principal veins; very rare on the calyxes, racemes and petioles [p].——Native of Guinea.]

70. Stem ſhrubby, two feet high, dividing into ſeveral woody branches, armed with ſharp thorns. Leaves ovate, woolly, having angular indentures on their edges; they are an inch and half long, and more than an inch broad. The flowers are produced in ſmall looſe axillary bunches; they are blue and large, appear in june and july, and are ſucceeded by round berries as large as common Cherries, of a gold colour, but turning black when ripe.

[Stem and whole plant tomentoſe, with very narrow naked prickles. Leaves green on both ſides, cordate, obtuſe, repand, commonly ſpiny along the midrib only: the young ones come out with a violet-coloured meal on the edge compoſed of ſtellate hairs. Berries fulvous, the ſize of a Gooſeberry [q].

β. Trunk two feet high, the thickneſs of the little finger, without hairs, but having a few ſhort prickles on it. Branches ſpreading, round, armed with ſtraight awl-ſhaped browniſh prickles. Leaves wide-ovate, ſubtomentoſe on both ſides, dirty green, blunt, repand, alternate, petioled; the midrib on both ſides and the petiole thinly ſet with prickles. Racemes oppoſite to a leaf, ſhort, almoſt unarmed, tomentoſe, ſimple. Calyx ſmall, tomentoſe, almoſt unarmed, deeply cut into five ovate and very ſpreading ſegments. Corolla deeply five-cleft, ſeveral times longer than the calyx, white or pale purple; ſegments ovate-lanceolate, acute. Berry the ſize of a Pea, red turning to a dirty orange-colour. Seeds pale with ſome yellowneſs [r]. It came to Jacquin from the Paris garden, under the name of S. coccineum. But it differs only in having whitiſh flowers, and a ſmaller fruit of a ſcarlet colour; for the leaves are not at all different. In the common *tomentoſum* there are ſometimes prickles and ſometimes none, and they are either very tomentoſe or have only a thin nap over them [s]. It is a native of the Cape of Good Hope, and was cultivated in 1731, by Mr. Miller [t].

71. Stem ſhrubby; branches round, below ſmooth with an aſh-coloured bark, above tomentoſe and yellow, as are alſo the branchlets. Leaves petioled, two or three inches long, having ſometimes a ſinus or two, but moſtly entire, veined on the upper ſurface, marked with lines along the nerves, rugged with minute ſtellate hairs: beneath nerved, tomentoſe with a yellowiſh nap, acute or obtuſe, ſubcordate at the baſe with a ſmall ſinus, and often ſhorter on one ſide of it. Spines on the branches, petioles, and frequently on the upper ſurface of the leaves, ſcattered, ſtraight, a quarter of an inch long, ſmooth, ſhining, yellow. Racemes lateral, peduncled, few-flowered, with a yellow nap on them, ſometimes bifid. Calyx ſhort. Corollas tomentoſe on the outſide, a little longer than the calyx, with ovate ſegments. There are often only four ſtamens; and ſome of the flowers are male.—Native of the iſland of Santa Cruz. Weſt [u].]

72. This riſes with ſhrubby ſtalks three or four feet high, dividing into ſeveral irregular branches, which have a gray bark, and are armed on every ſide with ſlender erect ſpines of a gray colour. Leaves an inch and half long, and half an inch broad, ſmooth, and a little indented or waved on their edges. Flowers in long bunches from the ſide of the ſtalk, upon long

peduncles, of a fine blue colour. Berries ſaffron-coloured, the ſize of peas.

[Cultivated in the Eltham garden, from ſeeds ſent from the iſle of Providence, one of the Bahama's [x]. It is alſo a native of Jamaica.

73. Shrubby. Branches purple, ſmooth at bottom, tomentoſe at top, prickly: prickles reflexed, yellow, ſmooth few. Leaves two inches long or more, acute at both ends, entire, a little ſhorter at the baſe on one ſide, flat at the edge, quite entire, having a few ſmall ſtellate hairs on the upper ſurface, ſlightly tomentoſe underneath, having ſometimes a ſmall prickle or two, but for the moſt part unarmed. Petiole an inch long, tomentoſe, prickly: prickles awl-ſhaped, ſtraight, fewer. Racemes above leafy, ſhort, nodding, tomentoſe. Corollas villoſe on the outſide: ſegments linear. Found by von Rohr in Cayenne [y].

74. This is a tree fifteen feet high, with the trunk as thick as the human arm or thicker, round, upright, aſh-coloured, with ſhort ſtout prickles, which are tomentoſe and ſpring from a wide baſe. Branches the ſame, but the younger tomentoſe and hoary. Leaves ſcattered, unarmed, lanceolate, acute, quite entire, wrinkled, ſmooth above, tomentoſe and hoary beneath, half a foot long, on tomentoſe unarmed petioles an inch in length. Racemes terminating, with the branches lengthened out beyond them, round, all unarmed together with the flowers, tomentoſe, moſtly twice dichotomous, three inches long. Pedicels many, directed one way, pendulous during flowering, but upright and an inch long when in fruit. Calyx ſmall, bell-ſhaped, tomentoſe, hoary, five-toothed. Corolla violet-purple, ſpreading very much: ſegments oblong, acute, flat. Filaments very ſhort. Berry roundiſh, ſhining, the ſize of a pea, red. Seeds roundiſh, compreſſed, whitiſh, ſeveral [z].

Vahl remarks that his *niveum* is allied to Swartz's *S. ſubinerme*, but is of a different country, and has very prickly branches, with the leaves ſnow-white underneath. Native of the Cape of Good Hope.

75. This is a ſhrub, with round flexuoſe branches, having two warts at intervals, below unarmed and ſmooth, above ſomewhat villoſe, hoary, with a few ſmall prickles. Leaves in pairs, one from five to ſeven inches in length, the other ſmaller by half, ſharp at both ends, a little narrower on one ſide of the baſe, ſomewhat rugged on both ſurfaces with indiſtinct ſtellate hairs, ſomewhat ſhining and unarmed on the upper, paler on the under ſurface with prickles along the midrib: prickles moſtly near each other in pairs, but ſometimes ſolitary and diſtant, ſmall, yellow, ſmooth, recurved. Petioles an inch long, one a little ſhorter than the other, having a few villoſe hairs ſcattered over them, and frequent prickles underneath. Peduncles lateral, filiform, half an inch long, aſh-coloured. Pedicels umbelled (probably becoming racemed,) a little longer than the peduncle, unarmed. Calyx alſo unarmed, mealy and ſomewhat villoſe, aſh-coloured, with awl-ſhaped ſegments. Corolla deeply four-cleft, with linear, ſomewhat villoſe ſegments. Filaments four. Anthers linear, almoſt the length of the corolla.—It is very nearly allied to S. obſcurum, which has alſo geminate leaves; but differs in having the branches more rigid and flexuoſe, the leaves larger and more attenuated, the prickles more frequent on the petioles, and four ſtamens. Nor is it very different from S. lanceæfolium, but it ſeems to be different in having flexuoſe branches, more ſparingly prickled, and four ſtamens.

Native of Cayenne, where it was found by von Rohr [a].

76. Stem round, upright, woody, with a duſky cinereous bark, weak at top, ten feet high, branched, green and ſhining above. Branches the ſame, weak and hanging down unleſs ſupported. Prickles on the ſtem and branches very numerous, ſhort, recurved, from a wide compreſſed baſe awl-ſhaped, pungent, orange-coloured at the tip. Leaves in pairs, lanceolate, acute at both ends, quite entire, ſhining on both ſides, but a little rugged to the touch on account of ſome white ſtellate ſeſſile hairs, viſible only with a magnifier: theſe are found alſo on the ſtem and branches. The leaves are dark green and unarmed on the upper ſurface, paler green on the under and prickly along the midrib only, from four to eight inches in length. Petioles about an inch and half long and prickly. Racemes lateral, ſharp, unarmed. Calyx ſhort and green, deeply cut; ſegments lanceolate-acuminate patulous. Petals white and deeply cut into lanceolate acute ſegments [b].

Native of South America.—Willdenow ſuggeſts that it is perhaps a variety of the preceding.

77. Stem branched, covered with ſcattered prickles. Leaves three inches long, brown above, tomentoſe and unarmed beneath. Flowers blue, large. Peduncles and calyxes unarmed.—Native of Mexico.

78. Stem and petioles tomentoſe; midrib of the leaves beſet all over with very ſhort capillaceous prickles. Leaves very like thoſe of Elæagnus anguſtifolius.—Native of South America [c].

79. Stem ſhrubby, round, the thickneſs of a pigeon's quill, villoſe-ſubtomentoſe with yellow ſtellate hairs; branches and midrib of the leaves on both ſides, having abundance of ſmooth, ſtraight prickles, a quarter of an inch in length, yellow with a brown tip. Leaves an inch and half long, narrow, equal at the baſe, ſubrepand or entire, having ſmall ſtellate villoſe hairs on both ſides, ſomewhat rugged, green. Peduncles ſolitary, very ſhort. Calyx ſtellate-villoſe, unarmed. Segments of the corolla linear, villoſe on the outſide. Stamens a little ſhorter than the petals. Berries globular, ſmooth, ſhining, the ſize of a Coriander ſeed [d].—Native of the iſland of Dominica.

80. This reſembles S. Bahamenſe very much, but the flowers are white, not violet; the leaves are acuminate, not bluntiſh; the ſpines are ſtouter, more abundant, and of a fiery red colour [e].]

Stem three feet high, dividing at the top into ſeveral branches, which are cloſely armed with ſtraight gold-coloured ſpines on every ſide. Leaves from two to three inches long, and three quarters of an inch broad, having a few angular indentures, and their midrib armed with a row of the like ſpines as thoſe upon the ſtalks, and ſtanding erect. Flowers in long bunches from the ſide of the ſtalks, white and ſucceeded by red berries almoſt as large as the ſmall black Cherry.

[Native of South America. Cultivated in 1714, by the Dutcheſs of Beaufort. It flowers from march to november [f].

β. This is a ſmall ſhrub. Stem round, ſcarcely the thickneſs of a pigeon's quill, ſmooth. Branches alternate, ſpreading, rod-like, ſtellate-villoſe at top. Prickles ſcattered over the ſtem, branches, and midrib of the leaves on both ſides, near half an inch in length, a little wider at the baſe, round, rigid, purple, ſhining. Leaves on ſhort petioles, an inch or an inch and half long, quite entire, at the baſe a little revolute and narrower, bluntiſh, appearing to have villoſe ſtellate hairs on both ſides when examined by a magnifier, rugged, veinleſs: above green, when full grown almoſt naked, marked with lines along the nerves, which ſtand out underneath, and there the leaves are paler, the hairs being cloſer; the tender leaves are ſubtomentoſe. Racemes lateral and terminating, ſimple. Peduncle filiform, looſe, two inches long or a little more. Pedicels remote, ſcarcely an inch long, thickened upwards; when bearing fruit reflexed. Segments of the corolla narrow, villoſe on the outſide. Berries ſmooth, even, ſhining, the ſize of a Coriander ſeed.—It is very nearly allied to S. igneum, and differs from it chiefly in the ſtem and branches being more tender; the leaves ſeveral times ſmaller and leſs attenuated; and the prickles twice or thrice as long.—Sent from the iſland of Santa Cruz by Weſt [g].

81. Diſtinct from the next ſpecies by its pinnatifid leaves, much ſmaller white flowers, and other marks. It ſeems to be allied to S. capenſe, and yet to be different [h].

[x] Dill. elth. [y] Vahl. [z] Jacqu. collect. [a] Vahl. ecl. [b] Jacqu. collect. [c] Willdenow. [d] Linn. ſpec. [e] Hort. kew. [f] Vahl. ecl. [g] Willdenow.

This, which is the *trilobatum* of Linneus's ſpecies, is named by Jacquin *Solanum* Milleri, being ſuppoſed to be his *S. Schia-Schuna* (n. 32.) Miller deſcribes it thus.] It is an annual plant, riſing with a prickly ſtalk near two feet high, ſending out a few branches without order. Leaves oblong, indented like winged leaves. Flowers in long bunches from the ſide of the ſtalks; they are ſmall, white, and ſucceeded by red berries the ſize of ſmall Cherries, which ripen in the autumn. He ſays it grows naturally on the coaſt of Malabar: [but according to others it is a native of the Cape of Good Hope, and perennial.

82. Stem ſuffruteſcent, high, narrow. Leaves ſmall, ſmooth, obtuſe, three or five-lobed, and ſometimes but ſeldom lobed at the baſe. The ſtem, petioles, leaves and peduncles have reflexed prickles. Peduncles one-flowered. Calyxes very ſmall, ſometimes with prickles and ſometimes without. Style aſcending. Flowers large, violet-coloured. Berries ſmall, like thoſe of Elder [h].

Linneus ſuſpected that this and the preceding were two different ſpecies, though he did not ſeparate them; but the leaves are never pinnatifid, the flowers are in racemes, four times as large and more, and of a violet colour [i]. Willdenow having ſeen only the Eaſt-Indian plant, which is very well figured by Burmann, does not undertake to determine whether the Jamaica plant be the ſame. If it be, this ſpecies is native both of the Eaſt and Weſt Indies.

83. This is a ſhrub with the appearance of Lycium. Stem unarmed, but all the branches end in a ſpine. Leaves ſmall, lanceolate-ovate or broad-lanceolate, leſs acute, even on both ſides, petioled. Corollas wheel-ſhaped, ſlightly five-cleft. The calyx has five acuminate teeth. Anthers ſhorter than the corolla, yellow, erect, gaping at the top. Stigma aſcending. Flowers lateral, ſolitary. Suppoſed to be a native of Peru [k].

84. Stem three feet high, with diffuſed branches. Leaves ſharpiſh, quite entire, villoſe on both ſides alternate. Flowers white, lateral; peduncles in pairs with one flower on each. Calyx ten-cleft, with awl-ſhaped ſegments. Berry ſmall, roundiſh, red.—Native of China and Cochinchina.

85. Branches long and twiſted. Leaves ſcattered, petioled. Flowers lateral, white. Berries middle-ſized, globular, green ſpotted with white, eſculent. The root is accounted good in the tooth-ach.—Native of Amboyna and Cochinchina.

86. Stem hairy, diffuſed, branched. Leaves alternate, quite entire, tomentoſe, petioled. Flowers lateral, on dichotomous peduncles. Berries ſmall, globular, red.—Native of China, about Canton.

87. Stem long, cloſely ſet with prickles, branched. Leaves ovate, five-lobed, villoſe on both ſides, with ſhort, curved, very ſharp prickles ſcattered over them. Flowers pale violet, ſmall, peduncled. Calyx four-cleft. Corolla wheel-ſhaped, four-parted. Berry very ſmall, round, deep red, ſhining, many-ſeeded.—Native of Cochinchina [l].]

88. Stems ſhrubby, trailing, two feet long, armed with long yellow ſpines, and covered with a gray bark. Leaves near four inches long, and almoſt two broad, very finely cut in form of winged leaves almoſt to their midrib; they are woolly, and armed along the veins with long ſlender yellowiſh ſpines on both ſides. Peduncles axillary, two or three inches long, each for the moſt part ſuſtaining two large yellow flowers, in very prickly calyxes; ſucceeded by ſmall round berries, the ſize of gray peas, and marbled green and white.—Diſcovered by Houſtoun at La Vera Cruz in New Spain.

89. Stem ſhrubby, five or ſix feet high, armed with ſhort recurved ſpines, and covered with a ſmooth browniſh bark. Leaves oblong, ſix inches in length, and two and a half in breadth, regularly ſinuated on both edges in form of winged leaves; theſe riſe by two or three from the ſame point, and ſtand erect; they are armed with a few ſhort ſpines along the midrib on both ſides. The flowers come out in ſmall looſe bunches from the ſide of the branches, to which they ſit cloſe; they are ſmall and white; the berries are about the ſize of thoſe of Juniper, and when ripe are red. This alſo was found by Houſtoun at La Vera Cruz.

90. Stalk ſhrubby, climbing, ten or twelve feet high, covered with a ſmooth brown bark, and dividing into ſeveral branches. Leaves ovate, woolly on their under ſide, but of a dark green on their upper; they are two inches long, and an inch and half broad. The flowers come out ſingly from the axils; they are large, of a fine blue colour, not divided into ſegments, but have five angles, each ending in a point. Berries round, about the ſize of gray peas, and red when ripe. Diſcovered by Houſtoun at La Vera Cruz.

91. Stalk ſhrubby, four feet high, having a white downy bark, and armed on every ſide with ſtraight brown ſpines. Leaves three inches aſunder, ovate with ſinuate indentures, two inches long, and an inch and quarter broad, woolly on their under ſide, on prickly foot-ſtalks; midrib armed with two or three ſmall ſpines, ſometimes on both ſides; all erect. Flowers in a ſeſſile umbel at the end of the branches; large, of a fine blue colour, in woolly calyxes. Berries round, the ſize of large peas, round when ripe. Diſcovered by Houſtoun at La Vera Cruz.

92. Stalk woody, ten or twelve feet high, ſending out many branches, which have a light gray bark, and are ſmooth. Leaves five inches long, and an inch and half broad in the middle, drawing to a point at both ends; of a deep green colour on their upper ſide, but hoary on their under. The flowers are produced in large umbels at the end of the branches; they are ſmall, ſtar-pointed, and white; their anthers, which fill up the mouth of the tube, are purple. Berries the ſize of middling peas, yellow when ripe. Diſcovered by Houſtoun at Campeachy.

93. Stalk ſhrubby, covered with a light-brown bark, and dividing into ſeveral irregular woody branches. Leaves ovate, four inches long, two and a half broad, ſmooth, dark-green on their upper ſide, but woolly on their under. Flowers in large erect umbels at the end of the branches; pretty large, and white. Berries round, the ſize of ſmall Cherries, ſitting in the blunt woolly calyx, and turning yellow when ripe.—Diſcovered at Carthagena in New Spain by Houſtoun.

PROPAGATION AND CULTURE.

2, 29, 55, 61, 63, 70, 81, and the ſpecies from the Cape of Good Hope, require an open airy glaſs-caſe or warm greenhouſe in winter, but in ſummer may be placed abroad in a ſheltered ſituation.

2 and 29, may be increaſed by cuttings planted in a ſhady border, during any of the ſummer months; when rooted, take them up, plant them in pots, and place the pots in the ſhade, till they have taken new root.

55, 61, 63, 70, 81. Sow the ſeeds on a hotbed, managing them as directed for the more tender ſorts; with this difference, that they may be much ſooner expoſed to the air, and ſhould not be brought up ſo tenderly. They are preſerved for their odd appearance; and their fruits being ripe in winter, afford a variety then in the greenhouſe; and their leaves and flowers being remarkable in their colour, ſhape, &c. they deſerve a place in every good collection of plants.

6. Sow the ſeeds in a pot of rich earth in the ſpring, place it in a moderate hotbed, and water the earth frequently. When the plants are come up, plant them in another moderate hot-bed, covered with rich earth about ſix inches thick, at ſix inches diſtance every way; arch the bed over with hoops, cover it occaſionally with mats, to ſhade the young plants from ſun and cold, and water them frequently.

When the plants have acquired ſtrength, and the ſeaſon becomes favourable, inure them by degrees to the open air, and expoſe them fully to it in june, when they ſhould be taken up, with a ball of earth to the root of each plant, and placed ſeparately in pots filled with rich earth in a ſhady ſituation, and frequently watered until they have taken new root; after which remove

[h] Linn. ſpec. [i] Willdenow. [k] Linn. mant. [l] Loureiro.

Digitized by Google

remove them to a more open expoſure among other exotic plants, giving them plenty of water in dry weather.

In the winter remove them into the greenhouſe, placing them in the coldeſt part where they may have as much free air as poſſible in mild weather, for they require only to be ſheltered from ſevere froſt, and are ſo hardy as many times to endure the cold of our ordinary winters abroad.

Shift the plants annually about the end of april, paring the roots round, cutting off all the mouldy fibres next the pot, and filling up the pots with freſh rich earth, to ſtrengthen the flowers, and cauſe plenty of fruit, which being of the ſhape and ſize of Cherries, are commonly called Winter Cherries by the gardeners.

15. The varieties of the Woody Nightſhade may be eaſily propagated by laying down the branches, or by planting cuttings in the ſpring upon a moiſt ſoil, where they will ſoon take root, and may afterwards be tranſplanted where they are to remain.

The African variety, which is probably a diſtinct ſpecies, muſt be preſerved in the greenhouſe in winter, and treated like n. 6.

31. The POTATO,

Is generally propagated by its roots, which multiply greatly if planted in a proper ſoil. The common way is, either to plant the ſmall roots or offsets entire, or to cut the larger roots into pieces, preſerving a bud or eye to each; but neither of theſe methods is what I would recommend, for when the ſmaller offsets are planted, they generally produce a greater number of roots, but theſe are always ſmall; and the cuttings of the larger roots are apt to rot, eſpecially if wet weather happens ſoon after they are planted; therefore what I would recommend is, to make choice of the faireſt roots for this purpoſe, and to allow them a larger ſpace of ground, both between the rows, as alſo in the rows, plant from plant; by which method I have obſerved, the roots have been in general large the following autumn.

The ſoil in which this plant thrives beſt, is a light ſandy loam, not too dry or over moiſt; this ground ſhould be well ploughed two or three times, in order to break and divide the parts; and the deeper it is ploughed, the better the roots will thrive. In the ſpring, juſt before the laſt ploughing, there ſhould be a good quantity of rotten dung ſpread on the ground, which ſhould be ploughed into the ground the beginning of march, if the ſeaſon proves mild, otherwiſe it had better be deferred till the middle or latter end of that month; for if it ſhould prove hard froſt after the roots are planted, they may be greatly injured, if not deſtroyed thereby: but the ſooner they are planted in the ſpring, after the danger of froſt is over, the better it will be, eſpecially in dry land. In the laſt ploughing, the ground ſhould be laid even, and then the furrows ſhould be drawn at three feet diſtance from each other, about ſeven or eight inches deep. In the bottom of this furrow the roots ſhould be laid at about one foot and a half aſunder; then the furrow ſhould be filled with the earth which came out, and the ſame continued through the whole field or parcel of land, intended to be planted.

After all is finiſhed, the land may remain in the ſame ſtate till near the time when the ſhoots are expected to appear above ground, when the ground ſhould be well harrowed over both ways, which will break the clods, and make the ſurface very ſmooth; and by doing of it ſo late, it will deſtroy the young weeds, which, by this time, will begin to make their appearance; and this will ſave the expenſe of the firſt hoeing, and will alſo ſtir the upper ſurface of the ground, which, if much wet has fallen after the planting, is often bound into a hard cruſt, and will retard the appearance of the ſhoots.

As I have allotted the rows of Potatoes at three feet diſtance, it was in order to introduce the hoe-plough between them, which will greatly improve theſe roots; for by twice ſtirring and breaking the ground between theſe plants, it will not only deſtroy the weeds, but alſo looſen the ground, whereby every ſhower of rain will penetrate to the roots, and greatly improve their growth; but theſe operations ſhould be performed early in the ſeaſon, before the ſtems or branches of the plants begin to fall and trail upon the ground, becauſe after that, it will be impoſſible to do it without injuring the ſhoots.

If theſe ploughings are carefully performed between the rows, and the ground between the plants in the rows hand-hoed, it will prevent the growth of weeds, till the haulm of the plants cover the ground; ſo that afterward there will be little danger of weeds growing ſo as to injure the crop; but as the plough can only go between the rows, it will be neceſſary to make uſe of a hoe to ſtir the ground, and deſtroy the weeds in the rows; and if this is carefully performed in dry weather, after the two ploughings, it will be ſufficient to keep the ground clean until the Potatoes are fit to take up.

In places where dung is ſcarce, many perſons ſcatter it only in the furrows, where the roots are planted; but this is a very poor method, becauſe when the Potatoes begin to puſh out their roots, they are ſoon extended beyond the width of theſe furrows, and the new roots are commonly formed at a diſtance from the old, ſo will be out of the reach of this dung, and conſequently will receive little benefit from it. And as moſt of the farmers covet to have a crop of Wheat after the Potatoes are taken off the ground, ſo the land will not be ſo thoroughly dreſſed in every part, nor ſo proper for this crop, as when the dung is equally ſpread, and ploughed in all over the land, nor will the crop of Potatoes be ſo good. I have always obſerved, where this method of planting the Potatoes has been practiſed, the land has produced a fine crop of Wheat afterward, and there has ſcarce one ſhoot of the Potatoe appeared among the Wheat the following ſeaſon, which I attribute to the farmers planting only the largeſt roots; for when they have forked them out of the ground the following autumn, there have been ſix, eight, or ten large roots produced from each, and often many more, and ſcarce any very ſmall roots among them; whereas, in ſuch places where the ſmall roots have been planted, there has been a vaſt number of very ſmall roots produced; many of which were ſo ſmall as not to be diſcovered when the roots were taken up, ſo have grown the following ſeaſon, and have greatly injured whatever crop was on the ground.

The haulm of theſe Potatoes is generally killed by the firſt froſt in the autumn, when the roots ſhould be taken up ſoon after, and may be laid up in ſand in any ſheltered place, where they may be kept dry, and ſecure from froſt. Indeed the people who cultivate theſe roots near London, do not wait for the decaying of the haulm, but begin to take up part of them as ſoon as their roots are grown to a proper ſize for the market, and ſo keep taking up from time to time, as they have vent for them. There are others likewiſe, who do not take them up ſo ſoon as the haulm decays, but let them remain much longer in the ground; in which there is no hurt done, provided they are taken up before hard froſt ſets in, which would deſtroy them, unleſs where the ground is wanted for other crops; in which caſe, the ſooner they are taken up the better, after the haulm is decayed. When theſe roots are laid up, they ſhould have a good quantity of ſand or dry earth laid between them, to prevent their heating; nor ſhould they be laid in too large heaps, for the ſame reaſon.

The kitchen-gardeners and farmers who live in the neighbourhood of Mancheſter, cultivate great quantities of this root, as the inhabitants of that populous town conſume abundance of them, and are much fonder of them than of any other eſculent plants; which has occaſioned an emulation among the cultivators, of endeavouring to outvie each other, in getting the roots of a proper ſize for the table early in the ſeaſon: in order to obtain this, they have made choice of thoſe roots which produced the firſt flowers, and have left them to ripen their ſeeds, which they have ſowed with great care; and the plants ſo raiſed, have generally been forwarder than the other; and by frequently repeating

Digitized by Google

peating of this, they have ſo much improved the forwarding of the roots, as to have them fit for uſe in two months after planting; ſo that great improvements may be made by this practice, of many eſculent plants, by perſons who are curious and careful in trying the experiments.

[Soil.

That a dry ſoil is much to be preferred for Potatoes, ſeems well aſcertained. Where ground is not naturally ſo, attention ſhould be had by all poſſible means to lay it dry. In wet ſpots this root is always watery, inferior both in quantity and quality. It is certainly improper for very ſtrong land, and will not grow to any purpoſe on a deep blue clay. In a heavy moiſt ſoil, the Black Potato, if any, ought to be planted: and the Howard has been found to proſper on a wet hungry gravel. Loams are preferable for this crop, but there is a difference of opinion upon the quality of this ſoil beſt adapted to it. Some recommend a rich loam; whilſt others ſay that very rich loams may indeed produce great crops and large roots; but that they are always inferior in flavour and mealineſs to thoſe which are raiſed on lighter ſoils. The ſoil about Ilford in Eſſex however, on which the beſt crops are grown, is a ſtrongiſh loam, not quite approaching to clay.

The ſoil which I (ſays Dr. Hunter) would prefer above all others, for this plant, is the ſame which Columella recommends for vines. Neither too ſtiff and untractable, nor too light and crumbling, yet rather of the crumbling kind; neither too poor nor too rich, yet inclining to richneſs; neither too flat nor too hilly, but rather gently riſing; neither quite dry, nor yet ſurcharged with moiſture. With ſuch a ſoil, and proper management, a noble return may be expected; and the nearer any ſoil approaches to this, the more ſuitable it will be to the cultivation of the Potato. But even from ſoils, not bleſſed with all theſe deſirable qualities, very beneficial crops may be obtained, if a little more labour and pains are beſtowed upon the neceſſary operations [m].

It is pretty generally known that an old graſs ley, lay or layer is an excellent preparation for Potatoes, without dung. In Ireland it is a very general method of breaking up old graſs land, to let it at very high rents to the labouring people to plant Potatoes on. They either plough or dig it; the produce is largeſt with the latter operation; but whether ſo much larger as to balance the difference of expenſe may be doubted. If there be no dung, the land muſt be good or the lay old. After all, many do not eſteem this ſo good a way as on ſtubble. In Lancaſhire, a ſward or freſh ley is reckoned moſt deſirable. Old lay near Frodſham in Cheſhire is let to labourers at the rate of 16l. an acre, and no manure allowed. At Knutsford in that county, old graſs dug produced five hundred buſhels an acre.

Many parts of Waſte lands, Commons and Heaths may be broke up with advantage for this purpoſe, either by ploughing directly, or by paring and burning.

Moſſes, Bogs and Moor-lands are well adapted to the culture of Potatoes, when properly drained; their parts being eaſily ſeparable, and the roots finding plenty of room to extend, and ſwell to their full ſize. In Ireland very conſiderable improvements have been made in this way, and it has been found that no ſoil produces a larger quantity of Potatoes than black moſs, or peat mixed with earth, that very great crops are gained from bogs well drained, that they eſcape the froſt, when they are killed in the highlands, and that theſe lands make excellent meadows. In Scotland alſo and the north of England, the Potato culture for improving moſſy ſoil is generally acknowledged to be of great advantage, and to be the beſt means of bringing ſuch waſte lands into culture. The crops in many inſtances have been ſaid to be even larger and more productive than in lower and more cultivated diſtricts [n].

[m] Eſſays, 2. p. 302.
[n] Young's Iriſh tour. Agric. Reports, and Report of the Committee of the Board of Agriculture, p. 7.

On Woodlands grubbed, no other crop ſeems better adapted than Potatoes, to bring the land into order, for culture of any ſort [o]: the ſoil being ſufficiently broken by the planting and taking up, and rendered perfectly clean by repeated hoeings.

In young Plantations of trees, the intervals cannot be put to a better uſe than to plant them with Potatoes, the ſeaſon after the young trees are put into the ground. In Shropſhire, Lord Clive allows the neighbouring cottagers to plant them; and if it be new ground, no manure is put in for the firſt two years. The culture is of great uſe to the young trees, but the Potatoes are not continued above three years. Mr. Coke alſo, of Holkham in Norfolk, permits the labourers to plant Potatoes in his young plantations, and finds the cultivation beneficial to his trees. In all caſes where the benefit to the planter and to the poor ſeems to be ſo reciprocal, as in this practice, it is much to be wiſhed that the ſame ſyſtem may be adopted [p].

Almoſt every farmer may procure this advantage for himſelf or his labourers, by planting or permitting to be planted Potatoes, in the corners of arable incloſures, where the plough cannot reach, on balks, headlands and other vacant patches of ground; which, when freſh, will bring a tolerable crop, without manure; the land, after the Potatoes are off, is ready for any other crop; and the labourers can plant and clean them in the mornings and evenings.—Or the farmer may make the crop the joint property of himſelf and his workmen; he finding land, manure and ſets, and they the labour: the produce to be equally divided [q].

Manuring.

The richer the land, the more abundant will be the crop, provided the ſoil be proper for it. Good freſh land may do without manure, but let not the farmer truſt too much to the ſtrength of his ſoil, to the excluſion of manure. Dung is the moſt uſed for Potatoes, and is in general the beſt manure they can have. Horſe-dung well rotted is by many reputed the beſt; next to that hog-dung; and after that night-ſoil and other ſorts of animal dung. In Eſſex from fifteen to twenty loads of rotten dung, are laid upon an acre, juſt before planting. Some good judges direct not leſs than twenty loads, of thirty buſhels each, well rotted [r]. In Cheſhire they lay from twenty to forty tons upon a ſtatute acre. In Weſtmoreland, one hundred loads on a cuſtomary acre of 6760 ſquare yards [s]. Mr. Dann prefers long dung, twenty-two loads to the acre [t]. In Lancaſhire long dung from the yard is uſed; but dung from great towns is ſuppoſed to produce moſt effect [u].

Limeſtone gravel is the general manure in many parts of Ireland. From three to four hundred one-horſe cart-loads are laid on an acre. They ſpread it on the fallow, after the firſt ploughing. The expenſe is about 1l. 11s. 6d. and it will laſt from fifteen to twenty years [x].

Lime is ſometimes uſed, but in general it is condemned as a manure for Potatoes. It has had however a good effect, mixed with peaty earth, at a much cheaper rate than dung [y]. In Dumfrieſſhire liming is reputed eſſential to prevent the rot, from which they had ſuffered greatly before they adopted this practice, but never ſince [z]. And freſh lime ſown over the ſurface two days after planting is a preſervative from the grub [a]. Lime, marl, ſoaper's aſhes and rags are affirmed by ſome to do little good, and in ſome inſtances to do harm, by making the roots ſcabby [b]. If lime be applied to the Potato crop, it ought to be laid on the ſurface, and wrought there by the hoeing, or laid on the land with the preceding crop; becauſe if it be much about the roots, although it may not hurt the flavour, it generally frets the ſkin [c].

On many parts of the coaſt and in the Iſle of Man they uſe Sea-weed or Sea-ware, (called in the Weſt Ore-weed,) and ſea-ſand, with or without dung. In

Digitized by Google

ſome parts of Scotland they affirm, that with this manuring, the roots are inclined to be tough and watery.

Coal-aſhes and the ſweepings of ſtreets may be uſeful in heavy ſoils. Some perſons are ſaid to have had good crops by uſing ſaw-duſt, fern or leaves of trees, and furze, or green broom chopped ſmall, for manure. The refuſe of peat-ſtacks, peat-aſhes and wood-aſhes, ſoot and bones are affirmed to be excellent; alſo the rubbiſh of mud-walls or cob. Gypſum or plaſter or alabaſter, was uſed by Mr. Weſton of Leiceſter.

Green crops, of Vetches, Clover, &c. covered in by planting, form a good manure for Potatoes.

In the courſe of Mr. Young's experiments on manure for Potatoes, it appeared that Urine yielded the moſt abundant crop. Upon which he remarks, that dunghills ought to be managed in ſuch a manner as to ſave, if poſſible, every drop of it[d].

When dung is uſed as a manure for Potatoes, the mode of application is different. Some lay it only in the places where the ſets are put, others all along the furrows, others again ſpread it equally over the land: ſome place the ſets over the dung, and others under it. The former is the better mode; and where plenty of dung can be procured or afforded, it is far preferable to ſpread it equally, for the ſake of the enſuing crop.

Tillage.

1. *On Lazy Beds.*

In this method of tillage, the land is laid out in beds with the ſpade, five, ſix, eight or ten feet wide, having trenches between them from two to three feet and a half and even four feet in width, ſometimes eighteen or twenty inches in depth. When theſe trenches are marked off with a line and ſpade, the dung is laid on the bed, and then the ſets in rows acroſs the bed, at ſuch diſtances as to allow room for a hoe. The firſt ſpit from the trench is laid on the Potatoes, with the graſſy ſide downwards, if the land be new; a ſecond ſpit of mould is taken and ſpread over to fill up the openings. When the young ſhoots appear, another ſprinkling of earth is given from the trenches; and the hoe ſucceeds when it is neceſſary[e].

This practice, which is general in Ireland, eſpecially among the cottars, may be adopted with propriety upon bogs, moſſes and moors partially or wholly drained, and upon ſuch rough ſoils as are difficult to plough. A good method with ſuch lands, is to pare and burn the ſurface, and to add lime to the aſhes. Strike the land into ſtraight beds ſix feet wide, with intervals of two feet, or two feet and a half. Lay the ſets twelve inches ſquare on the beds, and cover them two or three inches deep with ſpades from the intervals; when the plants appear, cover them again in the ſame manner, one and a half or two inches more. Keep them clean by one hand-hoeing and ſucceſſive weeding. They may be taken up with the plough by ſplitting the beds, and filling the former intervals; converting the open furrows left in the middle of the former beds into drains, deep enough to leave the land dry in winter.

Near Dublin, they make the beds ſeven feet broad; the trenches three feet and a half wide, and from eighteen to twenty inches deep, to bring up ſome limeſtone gravel; they always lay on 320 one-horſe loads of dung, ſix to a ton[f].

In ſome parts of Scotland and the Weſtern Iſlands this method has been adopted. Alſo in the Iſle of Man, on coarſe ſoils: the beds from ſix to ten feet wide; the trenches from two to three feet; the manure ſpread on the ſurface of the beds; the cuttings placed at ten inches aſunder, on the dung, and covered with the earth out of the trenches; when the plants appear, they give a ſecond covering of finer mould; the two together four inches deep: after this they hoe and weed[g].

In England, the lazy-bed method has not been received, except in a few diſtricts. It is practiſed however in Cheſhire: they plough the land before Chriſtmas; in april they plough it acroſs and harrow it, then plough it deeply into beds five feet wide: at the end of april or the beginning of may, the ſets are dibbled in eight or ten inches aſunder. In three weeks, or as ſoon as the buds appear, trenches are dug between the beds, and the plants covered with two inches of ſoil, ſpread equally: they are then hoed and weeded; and the crop is dug out[h]. By this method the Frodſham plants are allowed to produce the greateſt quantity in the kingdom[i]. Mr. Billingſley, on comparative experience, prefers this method to drilling. He makes his beds five feet wide, the alleys or intervals three feet, the ſets are placed a foot apart, covered not more than three inches with earth[k]. Mr. Parkinſon, of Doncaſter, produced from lazy-beds 2904 pecks, and by common digging only 1210: ſuperiority of the former 1694 pecks[l]. Mr. Macro on the contrary, an experienced farmer in Suffolk, found that ſets planted in the Iriſh faſhion yielded the leaſt, though planted the thickeſt of any. In ſubſequent experiments therefore he dropped this method, finding it to be far the moſt expenſive, and to leave the land very uneven[m]: nor will it ever probably be generally adopted in England[n].

Dr. Hunter has given ſome experiments recommending one, two, three or more ſets to be planted in ſmall hillocks, after the manner of Hops, at four feet ſquare. On the 14th of april he cut a large white Potato into ſeventeen ſets, which were planted in as many hillocks. The plants were earthed up, and on the 14th of october the crop was taken up. The produce was ten pecks of ſizeable Potatoes. Three or four ſets were put into other hillocks, but did not produce a greater crop than the others[o].

2. *By Drilling.*

The method of drilling by the plough in large concerns, and by the hoe in ſmall ones, appears to be much the cheapeſt, and in general is the beſt. It is uſually practiſed in England by thoſe who plant Potatoes on a great ſcale.

Soils liable to be wet during the winter ſhould be ploughed in autumn, ſo as to lie dry. In the ſpring plough and harrow flat. In march, april or may, according to the ſeaſon, and the nature of the land, draw furrows three feet aſunder, lay dung in them, not leſs than twenty tons to the acre; on this drop the ſets nine inches aſunder. If the land be ſtiff, cover the dung and ſets by drawing the earth over them with hand-hoes, adding more afterwards with the plough; if it be light and friable, they may be covered with the plough. Keep the intervals clean by ploughing or horſe-hoeing, for ſix or eight weeks after the Potatoes appear, afterwards by hand-hoeing: hand-hoe the rows when young, and afterwards weed them. Take up the crop by opening the rows with a plough, harrowing and picking more than once. In gardens and ſmall concerns, it may be taken up with the ſpade or the three-pronged fork.

Lands prepared and dunged for Wheat that could not be ſown, or where the plant has been deſtroyed or too much damaged to ſtand, are ready without farther manuring to receive Potatoes in this mode of culture: for which the above general directions may ſuffice.

It may be however a ſatisfaction to ſome perſons to be acquainted with the particular practice of eminent agriculturiſts, which they may adapt to their own peculiar circumſtances. Several of them therefore are here inſerted.

Mr. Young's directions in his Iriſh tour are as follow. Suppoſe the land to be a ſtubble. Spread the dung or compoſt equally over the whole, in quantity not leſs than ſixty cubical yards to a plantation acre. If the land be quite dry lay it flat, if inclinable to wetneſs arch it gently; in this firſt ploughing, which ſhould be given at the end of february or the beginning of march, the Potatoes are to be planted. Women are

to

Digitized by Google

to lay the ſets in every other furrow, at the diſtance of twelve inches cloſe to the unploughed land, that the horſes may tread the leſs on them. There ſhould be women enough to plant one furrow whilſt the ploughman is turning another; the furrows ſhould not be more than five inches deep, nor broader than nine inches, becauſe when the Potatoes come up they ſhould be in rows eighteen inches aſunder. The furrows ſhould alſo be ſtraight, that the rows may be ſo for horſe-hoeing. Having finiſhed the field, harrow it well to lay the ſurface ſmooth and break all the clods, and if the weather be quite dry any time in a fortnight after planting, run a light roller over it followed by a light harrow. About a fortnight before the Potatoes appear, go over the whole ſurface of the field with a ſhim, the cutting edge of which is two feet long, going not more than two inches deep; this looſens the ſurface mould, and cuts off the young weeds that may be juſt coming up. When the Potatoes are three inches high, horſe-hoe them with a ſhim that cuts twelve inches wide, and goes three inches deep, and immediately after hand-hoe the rows, cutting the ſurface well between plant and plant, and alſo the ſpace miſſed by the ſhim. Repeat both theſe operations when the plants are ſix or ſeven inches high; and in about three weeks after give a hand hoeing, directing the men gently to earth up the plants, but not to lay the mould higher to their ſtems than three inches. After this nothing more remains to be done than ſending women in to draw out any weeds that may appear by hand [p].

Theſe directions ſuppoſe the ſoil to be light and dry: Potatoes never anſwering, in Mr. Young's opinion, on clays or ſtrong wet ſoils. Wheat is intended to follow the Potatoes; then Turneps; next Barley; then Clover, and laſtly Wheat again, to be followed by Potatoes.

The following is the mode adopted by Thomas King, Eſq. of Kingſton in the county of Wicklow, for ſeveral years, in the culture of Potatoes.

The land for drill Potatoes ſhould be dry, and cleared of all impediments to the plough. The beſt preparatory crop, if the land be in graſs, is that of lay-oats. In ploughing the ground, lay the ſod all one way, with a turn-wreſt plough, rather deeper than the ſtaple ſoil, and harrow in the Oats immediately. As ſoon after theſe are off as convenient, plough the ſtubble well and deeply; if with the Kentiſh turn-wreſt plough, ſo much the better. Early in the enſuing ſpring, harrow well in dry weather, and then croſs-plough: previous to planting, harrow well again, and lay the ground as flat as poſſible.

If the land inclines one way much more than another, run the drills up and down hill, that they may be effectually moulded on both ſides by the hoe-plough; but if the ground be flat, or not much inclining, run the drills north and ſouth. The drills ſhould be three feet aſunder. Having determined that ſide of the field where it is intended to begin, meaſure nine yards from the line of the firſt intended drill, and on the ninth yard let a row of car-loads of dung be laid from one end to the other, allowing a ſufficient headland at each end for the plough and horſes to turn upon: which headlands, after the horſe-hoeing is finiſhed, may be ſown with Turneps, or any other crop ſuitable to the ſeaſon. When the firſt load of dung is laid down, let the next horſe be drawn up, until his head reaches the former load, and in like manner to the end of the row: ſuch a row is a good dreſſing for the Potatoes, and a ſucceeding crop of Wheat. It is ſuppoſed that two Iriſh car-loads contain little more than an Engliſh one-horſe cart-load.

When the dung is all out, and ſets prepared, ſix men and as many boys ſhould be placed along the drill, at equal diſtances. The drills may be made by a good ſwing-plough going and returning in the ſame furrow, in a line perfectly ſtraight, and as deep as the ſoil will permit, obſerving always, that if the ground hangs one way, the laſt ſtroke in opening the drill ſhould throw the mould out from the higheſt ſide of the land; which clears the drill much better than when the laſt ſtroke throws the mould againſt the drill, and much depends upon the drill being very clean. As the plough paſſes the firſt boy in completing the drill, he ſhould begin dropping ſets, not farther than five inches aſunder, the Potatoes having ſufficient room to ſpread ſideways. As the ſets are dropped, each man covers his portion with dung from the firſt row. If after the firſt drill is made, the driver walks in, making the ſecond drill quite cloſe to the firſt, and keeps his horſes cloſe up to his ſhoulder, the drills will be exactly three feet aſunder: but if the ploughman and driver be not expert, then it will be neceſſary to ſet up marks at due diſtances. By the time the firſt drill is planted and dunged, the plough will have opened another, which is to be planted and dunged as the former; and by the time the plough comes to the ninth drill, the firſt row of dung, will or ought to be exhauſted.

It is not neceſſary to cover the drills until the planting is finiſhed. A light harrow, ſomewhat raiſed by being buſhed, ſo as to prevent the harrow-pins from reaching the dung, which it would otherwiſe drag out of the drills, drawn acroſs, will effectually cover them: much better indeed than the uſual method of covering with the plough, and then harrowing to level: or the drills may be covered by a board edgeways, four inches deep, and four feet long, with a handle like that of a rake. Covering with the plough leaves the land uneven; the Potatoes in conſequence come not up in regular rows, which is a great inconvenience in horſe-hoeing.

When the plants are up ſo as diſtinctly to ſee the entire drill, the mould ſhould be turned from the plants by a light ſowing-plough; at firſt from one ſide of the drill only; and in three or four days, when that mould is returned, then from the other ſide. The plough ſhould be run up as cloſe to the plants as poſſible. If both ſides were ſtripped at the ſame time, and unfavourable weather ſhould happen, the plants would be materially injured.

Previous to the ſecond horſe-hoeing, which ought to be done in about a week from the former, the Cultivator, Nidget or Shim ſhould be run between the drills, to cut all the weeds in the intervals, and to raiſe mould for the next horſe-hoeing. If any weeds ſhould appear in the row, they ſhould be picked out by hand.

The horſe-hoeing, by which the mould is thrown up to the plants, ſhould be performed at leaſt four times, each time going and returning in the ſame interval; that is, once from and three times to the plants; but the oftener they are horſe-hoed the better, unleſs the planting be very late; then horſe-hoeing keeps the Potatoes too long in a growing ſtate, and there is not time for them to ripen fully.

A plough with a double mould board ſhould be uſed for finiſhing; it ſhould be very narrow in the ſole, the mould boards high, and at the upper part as wide behind as the interval, ſo as to preſs the mould home to the ſtems on both ſides at the ſame time. The intervals, when finiſhed, ſhould reſemble a celery-bed; deep at leaſt as the ſtaple mould, and neatly cleaned up on both ſides.

The whole expenſe of an acre thus planted is under five guineas; whereas in the common ridge way it amounts to fourteen pounds. The land is more improved by a drill crop with one hundred loads of dung, than by four hundred in the ridge way. Three drills are equal in produce to the beſt ridge, and generally much better.

The principal improvements of the above culture are, the aſcertaining the proper quantity and due diſtance of the dung:—drawing out the dung before any drills are made: ſuffering nothing to touch the drills when opened until they are planted and dunged; and then covering them again by croſs-harrowing.

In Lancaſhire, a ſward or freſh lay is preferred, but not always to be obtained. Good crops have been frequently raiſed from lands exhauſted. The ground being previouſly cleaned by ploughings, and planted in april, if the ground can be got into condition, in drills,

[p] Vol. 2. p. 399.

Digitized by Google

drills, about three feet diſtant, and from nine to twelve inches aſunder in the rows, the ſets are placed immediately upon long dung from the yard, &c.; but dung from great towns produces a wonderful effect upon lands not accuſtomed to that article.

The crops are kept clean from weeds by the plough, firſt by turning a furrow, left for that purpoſe, towards the young plants, as ſoon as they appear, and afterwards by turning the ſame furrow back from each ſide of the drill. Sometimes the crop, if very foul, is harrowed with a ſmall triangular harrow, running through each drill. After the weeds have been ſo expoſed, the furrow is turned back again, and ſometimes the ſame plough, or a double-wriſted one, runs up each drill once more; beſides the deſtruction of weeds, the ſoil, by thoſe operations, is looſened, and expoſed to the ſun and air, by which the crop is greatly improved [q].

In Kent, the dung is ploughed in, and then furrows are made twenty inches apart, in which pieces of Potatoes are dropped, fourteen inches aſunder, by hand, and then covered by ſplitting the furrows, or ſometimes with a planting-hoe. Or they are dibbled in, and the pieces dropped in every other furrow after the plough, whilſt turning in the dung.

In Northumberland the drills are from thirty-two to forty inches diſtant; and the ſets are placed twelve inches aſunder; the dung is laid upon them, and the ſoil is turned upon the whole, by the plough ſplitting the one-bout ridges. The crop is kept clean by hand-hoeing, and ploughing between the drills. As the ſtems advance, they are earthed up by a common or double mould-board plough [r].

In Lincolnſhire, Mr. Cartwright ploughs before Chriſtmas, again in march, and in april: the land being properly cleaned, about the middle of april, the dung (twelve three-horſe loads to an acre) is carted out; as ſoon as this is ſpread on three acres, three ploughs begin; and the length of the furrows being divided into ſixteen equal parts, one woman being ſtationed in each diviſion; and a man being fixed to every four women, he rakes the dung on to the Potatoes, after the women have laid the ſets in the furrows, a little on one ſide, to be out of the tread of the horſes. After planting, they are rolled down with a light roller. When they come up, harrow them lengthwiſe with light harrows. In three or four weeks horſe-hoe them; and when the weeds are dead, repeat it: then hand-hoe the rows. In a week or thereabouts, earth up with double mould-boards: and repeat this in two or three weeks after. Laſtly, in auguſt hand-weed them [s].

In the North Riding of Yorkſhire Potatoes are generally cultivated as a fallow crop; of courſe the land is winter-ploughed, and made clean from weeds, as early in the ſpring as the ſeaſon will admit. The ſets are placed at ten inches diſtance in the furrows, the land having been ſet out in one-bout ridges with the plough. The manure (from ten to twenty cart-loads on an acre) being either ſet in heaps in the field, whence women and children take it in baſkets and lay it in the furrows over the ſets; or ſpread over the ridges, when it is pulled into the furrows with a moulding rake or hoes. They are then covered with earth by the plough dividing the ridge, and making a freſh one over the Potatoes. As ſoon as the plants make their appearance, the ridges are harrowed down, and remain in that ſtate about a week; they are then earthed up, and in a week or two as much of the earth from the ſides of them is ploughed down, as can be done, without leaving the roots too bare; after this, the tops of the ridges are carefully hand-hoed, and the earth which was ploughed from the ridges is again ploughed to them: if afterwards weeds ſhould grow, they are again hand-hoed or weeded, after which the earth is drawn up to the top of the ridges. The ſtems having by this time got to a conſiderable ſize, ſoon overcome all weeds, and conſequently require no farther attention till the time of taking up [t].

In the county of Argyll in Scotland, Potatoes are commonly planted on poor ground, after a crop of Oats. The ground is ploughed in winter and early in ſpring, and again a ſhort time before it is planted. It is alſo twice harrowed in the intervals. The drills are from thirty to thirty-ſix inches aſunder; the dung is laid in the furrows between them, generally over, but ſometimes under the ſets, which are placed from ſix to eight inches diſtant. The drills are then ſplit to either ſide, and the new drills formed over the Potatoes where the furrows were before. In about three weeks, the ground is harrowed acroſs the drills, and after the plants are come up, the earth is taken from them with the plough; ſoon after, it is put to them again; and after this they are twice hoed, earthing up the ſoil about the plants as much as may be, and going over it with the hand-hoe, to deſtroy the weeds which the plough may have left.

Some lay on the dung before the firſt, and ſome before the ſecond ploughing. In this way it is more intimately mixed with the ſoil, and will be of more ſervice to the ſucceeding crop, than when laid in one place at the bottom of the drill, where much of its ſubſtance muſt ſink down beyond the reach of the plough. When the dung is mixed with the earth, the Potatoes are drier; but they grow larger when all the dung is cloſe to them. But the addition to quantity will not compenſate for the defect in quality.

In any part of a field that inclines to wet, it is better to dibble in the ſets into about half the depth of the drill, than to lay them in the bottom, where they will be apt to periſh. Perhaps they are in general buried too deep, which makes them long in coming up, and later in ripening [u].

In the county of Fife, Potatoes being uſually cultivated as a cleanſing crop, they are introduced after white crops, as Wheat or Oats. The ground is commonly ploughed at the beginning of winter, and as completely looſened and pulverized as poſſible, by repeated ploughings. Thoſe who take land from the farmers ſeldom make the drills above eighteen or twenty inches aſunder, from an apprehenſion that wider drills will leſſen the quantity of the produce. But farmers, who do not labour under that prejudice, generally make the rows three feet, or at leaſt two feet and a half diſtant, and place the ſets from eight to ten inches aſunder in the row. By this method, whilſt an equally large crop is produced, an opportunity is afforded for repeated horſe-hoeings, which in cleaning foul land are more effectual than all the dreſſing that can be given merely with the hand-hoe. In ſome caſes the land is laid into three-feet ridges, and the dung ſpread along the furrows. The ſets are then dropped on the dung at proper diſtances. To lay the ſets in the furrow before the dung is ſpread, is a good method, and ſometimes practiſed. The ſets are covered either by ploughing the whole intermediate ridges at once, or by a ſingle furrow from each ſide, leaving the reſt untouched till ten days or a fortnight after.

Sometimes before planting the ground is harrowed, and the dung ſpread over the whole ſurface as evenly as poſſible. On each ſide of the ridge, beginning at one ſide of the field, a furrow is opened, and the ſets dropped along it: they are then covered with the plough; and after that, the plough goes twice or thrice round the ridge, before planting again, ſo as to bring the rows to their proper diſtance. And thus they proceed with every ridge, till the whole be completed. But it may happen, that if the hands employed in planting are too few, the plough muſt ſtand ſtill for ſome time; or if they are ſufficiently numerous to keep the plough conſtantly at work, then they muſt ſtand idle all the time the plough is employed in tilling the ſpaces between the rows. To ſave time and labour therefore, the planting ſhould be carried on upon two ridges at the ſame time; ſo that when the planters are at work on the one ridge, the plough may be employed on the other. And thus the farmer is not under the neceſſity of having more hands than can be kept conſtantly at work.

The ground is harrowed, when the Potatoes begin to appear, or a little before, to deſtroy the ſeed weeds. As ſoon as the rows can be diſtinctly obſerved, the earth is tilled away from the Potatoes; the plough, in this operation, being brought as near the plants as poſſible, conſiſtently with their ſafety. This contributes not only to deſtroy weeds, but to looſen the ground about the plants. The hand-hoe is employed to ſtir the ground, and deſtroy the weeds between the plants. If the land be ſtiff, and bound together with root-weeds, ſuch as couch-graſs, &c., theſe are torn up with the three-pronged hoe. In about ten days after, and when the weather is dry, the earth is laid back to the plants with the double mould-board drill plough. The number and ſeaſon of ſubſequent ploughings depend upon the ſtate of the land and the weather: but the laſt ploughing is generally done with the broad ſharp ſhare, and pretty deep. After which the mould may be drawn cloſe to the ſtems with light broad-teethed iron rakes, eighteen inches long in the head. Inſtruments of this kind will perform the work more expeditiouſly, and perhaps more completely, than hand-hoes[x].

In Mid-Lothian the ground is previouſly well pulverized by frequent tillage; and it is always the drieſt ſoil that is choſen, without regard to the preceding crop. The mode of culture is uniformly in drills, from eighteen inches to four feet diſtant from one another; and from nine inches to twelve, plant from plant. The dung is, in ſome caſes, ſpread over the whole field; in others, it is confined to the rows: ſometimes it is applied to the preceding crop, which is thought to make the beſt eating Potatoes, although rather leſs in quantity [y].

The Rev. Mr. Cloſe recommends the following culture, the reſult of various experiments made for five years ſucceſſively. The land being well pulverized by two or three good harrowings and ploughings, is then manured with fifteen or twenty cart-loads of dung to the acre, before it receives its laſt earth. Then it is thrown on to what the Suffolk farmers call the *trench balk*, which is narrow and deep ridge work, about fifteen inches from the centre of one ridge to the centre of the next. Women and children drop the ſets in the bottom of every furrow fifteen inches apart; men follow, and cover them with large hoes, a foot in width, pulling the mould down ſo as to bury the ſets five inches deep; they muſt receive two or three hand-hoeings, and be kept free from weeds; always obſerving to draw the earth as much as poſſible to the ſtems of the young plants. By this method, the ſets will be fifteen inches ſquare from each other.

If Potatoes be grown as a preparation for Wheat, the rows ſhould be two feet two inches from each other. Hand-hoe only the ſpace from plant to plant in each row: then turning a ſmall furrow from the inſide of each row by a common light plough; and afterwards with a double-breaſted plough with one horſe, ſplit the ridge formed by the firſt ploughing, thoroughly to clean the intervals. This work ſhould not be done too deep the firſt time, to avoid burying the tender plants; but the laſt earth ſhould be ploughed as deep as poſſible; and the cloſer the mould is thrown to the ſtems of the plants, the more advantageous it will prove. The land, by the ſummer ploughings, will be prepared to receive ſeed-wheat immediately, and almoſt enſure a plentiful crop [z].

Arthur Young, Eſq. planted four acres with Potatoes on a poor gravelly loam; an oat ſtubble on broad flat lands. Theſe were ploughed into the four feet ridge the beginning of november, and ſo left for winter. April the 14th following it was ploughed again reverſing the ridges, and immediately on this ploughing 283 loads of farm-yard compoſt were carted into the furrows; the ſets were planted in one row, twelve inches aſunder, along the middle of the dung, by women and children: a plough followed, which taking off a ſlice from the ſides of each ridge covered the Potatoes and the dung. There being much graſs and weeds in ſeveral parts of the field, the operation of reverſing the ridges was not completed then, that the ſun might have more power on the land, but the ſecond bout was done in a fortnight after, which left the ridges in their firſt form.

The 18th and 19th of june, the plants being about ſix inches high, a furrow was turned from the ſides of each ridge, leaving the plants upon a ſlip of a foot wide. This part of the horſe-hoeing ſyſtem appeared neceſſary before the hand-hoes went to work; for it turns every large knot of graſs and weeds from the plants into the middle of the intervals, where they are much more eaſily deſtroyed, and it leaves the plants far eaſier to hoe. Upon this they were hand-hoed; and on the firſt of july the intervals were harrowed flat with the horſe-hoe harrow, ſome parts of the field twice and thrice in a place, to tear the graſs in pieces, which it did ſo effectually, breaking the clods at the ſame time, that the ſun killed much of the rubbiſh. July the 5th they were hand-hoed a ſecond time; and as this was the laſt time, and every weed was therefore to be eradicated, it was done by the drag. As ſoon as the weeds of this hoeing were dead, the rows were earthed up with the double mould-board plough. Laſtly, on the 20th of auguſt and the following days they were hand-weeded.

Mr. Young finding from ſeveral ſmall experiments, that he had hitherto given his crops too much room to have a large produce, was led to try half an acre in another mode; the ſoil a good dry ſandy loam: the operations were moſt of them performed at the ſame time as thoſe deſcribed above. It was a barley ſtubble left through the winter, on which fifty loads of compoſt were ſpread over the whole ſurface; the plough then went in, and in reverſing the former flat lands, every other furrow was planted, the ſets at twelve inches aſunder; and as the plough carried nine inches, the Potatoes of courſe were in rows eighteen inches apart. Women laid, (not dropped,) the ſets cloſe to the unploughed ſide of the furrow, to eſcape as much as might be the horſes feet: as ſoon as planting was finiſhed, the land was harrowed twice, then rolled with a barley roller, and harrowed once again, leaving it in fine order. In about a fortnight or a little more, there was great appearance of ſeed-weeds coming up; as theſe threatened a heavy expenſe of hoeing, they were cut off with the horſe-hoeing ſhim. Nothing could anſwer better than this operation; care however ſhould be taken that the tool do not go ſo deep as to cut off any ſhoots that do not appear; nor ſhould it be done but in dry weather. It was then harrowed, and when the plants were three inches high the rows were hand-hoed: directly after the intervals were horſe-hoed with a ſhim, that cut only twelve inches wide. Both theſe operations were repeated once, and at the end of auguſt a hand-weeding being given, the crop carried a ſuperior appearance. The produce was 550 buſhels to the acre; whereas in the experiment above related it was only 390. The mode therefore here purſued of planting in cloſer rows is to be preferred, unleſs a field ſhould be exceedingly full of root-weeds, in which caſe wide intervals are uſeful for horſe-hoeing [a].

Mr. Young, in his latter experiments, carried on his dung, ſpread it, and ploughed it in early in november, being convinced by experience, that upon all ſoils, inclinable to wet, the manure ſhould be carted and ſpread either in the autumn or during a hard froſt, leſt the ſeaſon ſhould be wet at planting time, and the ground therefore poached by the horſes.

Mr. Young's laſt experiment was on twelve acres and a half, a cold but friable loam upon a clay-marl bottom, making the field wet for want of draining, having borne a crop of Oats. In november he ſpread 298 loads of farm-yard compoſt over eight acres; the reſt not manured at all. The whole was ploughed immediately. The firſt of may it was ploughed clean, and harrowed after the ploughs: to try a new method of planting, in which the mould would fall in the lighteſt manner poſſible on the ſets, the land was ſtruck with the common plough into furrows two feet aſunder,

and the ſets being dropped in theſe at twelve inches apart, were covered by running a pair of harrows up and down the furrows, and were then rolled and harrowed again. Nothing could work finer, drier, or in a manner more promiſing for a crop. One acre and a half was planted in this manner with the white cluſter Potato; two acres with the champion, a very fine table Potato that never curls, and the reſt of the field with the red cluſter. June the 2d, &c. the ſurface was cut with the great ſhim. It was the 16th before the rows were up plain enough to horſe-hoe; they were ſhimmed, and on the 19th harrowed acroſs, without damaging them. The 24th they were hand-hoed the firſt time. July 21ſt they were hand-hoed again, and ſhimmed a ſecond time. The ſeaſon had been for ſome time exceedingly wet, ſo that the weeds grew apace. The crop was hand-hoed again in auguſt, and earthed with the double mould board plough. The White cluſter did not produce nearly equal to the Red: and the dunged part of the field, yielded double the crop of red cluſter, to that which was not dunged [b].

It is well known that good crops of Potatoes can be obtained on gràſs lands, but ſome rabbet-warrens and waſtes may alſo be broken up for this purpoſe with ſucceſs. We have an inſtance of this near Crawley in Suſſex, where part of a rabbet-warren was incloſed, denſhired, and one crop of Oats taken from it; but the crop was ſo indifferent, that the land was again thrown open to the warren for two years. In october, 1796, it was again incloſed and ploughed up. It lay fallow till the middle of march, 1797; it was then harrowed, and in a few days afterwards croſs-ploughed. It remained in that ſtate till the firſt week in april, when it was again harrowed, and in a few days after ploughed a third time; in about ten days more it was harrowed a third time, and laid up in ridges for the reception of dung. Twelve cart-loads of indifferent fold-yard dung were then laid upon it; and before the 25th of april twenty buſhels to the acre of a mixed kind of Potatoes were planted upon it. In june the land was once hoed, and the Potatoes earthed up. The produce, taken up in october, was rather more than 250 buſhels to the acre, and it was applied to feeding and fatting cattle: 280 buſhels being reſerved for ſets, to plant on fourteen acres of warren land, without dung [c]. No account of this ſecond experiment having appeared, perhaps it did not ſucceed to Mr. Seaton's wiſhes.

One of the eaſieſt ways of bringing waſte lands into culture, is by planting them with Potatoes, eſpecially where it is not thought expedient to pare and burn. Cottagers and labourers might aſſiſt in this improvement, under proper regulations; for no great quantity of manure would be required at firſt breaking up, and they might collect fern and weeds, which mixed with their aſhes and offal, and ſome of the beſt mould or rotted turf, would make a good compoſt, to put in the drills or holes which are to receive the ſets. But perhaps ſuch lands may be better ſet by the following mode of

3. *Dibbling.*

This is practiſed on a large ſcale about Ilford and other places in Eſſex. The preparation here is an autumnal ploughing, dunging in the ſpring about fourteen loads an acre, ſpread on the field juſt before the ſecond ploughing, on which they plant. Immediately after the plough, a man dibbles acroſs the land, followed by a woman who drops the ſets; the rows fourteen inches by fourteen or fifteen, and ſome twelve ſquare. They are hand-hoed twice. They mow Clover and plough it up in july to plant immediately. Some perſons have taken two crops on the ſame land in a year; putting one in as ſoon as the other is taken up. They alſo plough and plant land, cleared of winter tares for ſoiling, and often get good crops from ſuch late planting. Some farmers have tried putting them in with a plough, and taking them up in the ſame manner, but from experience are convinced that the other method is much ſuperior [d].

Towards the weſtern parts of Cornwall, about Penzance, &c. they produce two crops of Potatoes in a year. They plant the kidney about Chriſtmas, or a few weeks ſooner, which they draw in may, and then, in the ſame ground, plant the apple Potato. But this mode of forcing crops is not to be generally recommended. By the common mode of planting at the end of april and beginning of may, after paring and burning, 450 to 600 Wincheſter buſhels are no uncommon produce. The ſoil and climate of this part of the kingdom are adapted to this plant, the ſummers being always moiſt, and the ground warm and dry. The weſtern iſles of Scotland are fully as moiſt, if not more ſo than Cornwall, or the weſtern parts of Ireland. The iſles of Canna, Tiree, &c. have moſt excellent crops of Potatoes, with the ſame kind of dreſſing as is uſed in Cornwall, that is, ſea-ſand, ore-weed and dung. Theſe iſlands are however comparatively much colder than Cornwall, and yet their produce, in the article of Potatoes, is greatly ſuperior to the inland parts of Scotland in the ſame latitude. The produce of Potatoes, in the weſt of Ireland, is alſo known to be extremely abundant.

In the iſles of the Hebrides mentioned above, the ſoil is dry and porous, containing a great mixture of ſea or ſhell ſand, and is much of the ſame nature as the ſoil about Penzance and other parts of the weſt of Cornwall. All this proves the propriety of cultivating Potatoes where the ſoil is dry and the climate moiſt [e].

In the Midland counties, the practice in planting Potatoes, runs much upon dibbling. Contrary to the practices of moſt other diſtricts, ſays Mr. Marſhal, they almoſt invariably ſucceed turf. The plough is ſeldom if ever uſed. The ſoil is broken up with the ſpade: ſometimes in two ſhallow ſpits, throwing the ſward, and the dung, if any be uſed, to the bottom; covering them, in the gardener's manner, with the under ſpit: but generally in one full ſpit, merely inverting the ſward, fitting the ſpits to each other, and leaving a ſmooth even ſurface of clear free ſoil. On this the plants are dibbled very thick, about the middle of april: they are hoed once, twice, or as often as circumſtances may require; the crop moſtly being managed in a gardenly manner.

Potatoes are ſometimes grown two years together on the ſame land; and in this caſe it is ſaid to have been found, that dibbling in the ſets, on the ſtale ſurface, as left, on taking up the firſt crop, or only levelled with the harrow, without any previous ploughing or digging, is the moſt eligible way of putting in the ſecond crop [f].

Dr. Wilkinſon, of Enfield, on ſoil generally rejected as improper for Potatoes, being a pebbly loam, produced 400 buſhels to the acre by dibbling. On a clover-ley, he had twelve loads of dung, ſpread immediately from the fold-yard on each acre. The ſets were put in with a dibble, on one ploughing: the rows eight inches aſunder, and the ſets ſix inches apart in the rows. The planting was done between the 5th and 22d of may. The field was hoed twice before the plants had riſen to any ſize above ground. This checked the growth of the weeds, and was the only hoeing that could be given, on account of the ſmall intervals between the ſets. The field was ſoon entirely covered with the ſtems, which ſmothered great part of the weeds, though the wet ſeaſon which followed occaſioned them to ſpring uncommonly thick [g].

Dibbling may very properly be practiſed on graſs land, on a clover-lay, on waſtes and moors, on ſands and very light dry loams in general; but on lands inclined to be ſtiff and to retain wet, or in wet ſeaſons, it is a very bad method. The hole made with a dibbler or ſetting-ſtick, eſpecially if it be ſhod with iron, hardens and glazes the earth round it, leaves a hole at the bottom, which if rain enſue ſoon after may probably be filled with water, whilſt the ſides are ſo hardened that the tender fibres of the roots will not eaſily ſtrike into them. Whereas in drawing a drill, the earth is left in a fine pulverized ſtate, and the ſet is afterwards lightly covered with ſimilar earth,

and

and conſequently the roots have fine ſoil to ſtrike into [h].

4. *By the Hoe.*

At Sandy in Bedfordſhire, a pariſh of farming gardeners, they plant Potatoes in a ſingular way. They dig or hoe holes, and dropping a ſet in each, cover them by the earth of the next row of holes: they riſe about one foot ſquare [i].

In the North Riding of Yorkſhire, though the practice of covering them with the plough is very common; yet the ridges are ſometimes hoed down upon the ſets by hand [k]. This is commonly done in other places, for ſmall and garden crops, when not ſet with a dibbler.

Of all the above methods drilling is in general the beſt, and that by lazy-beds the worſt, at leaſt where the ſub-ſoil or under-ſtratum of earth is not good. The Sandy method is very ſlovenly; all the others may in paticular circumſtances have the preference. But when the ground is not of any great extent, trenching, though the moſt expenſive, is far preferable to the reſt, and will often more than repay the additional expenſe [l]. This is commonly practiſed in kitchen gardens.

PLANTING.

The method of planting Potatoes, depends upon the mode of tillage that has been previouſly adopted, and has already been deſcribed, as to its general proceſs. The ſets may be put in too deep, and if they are out of all influence of ſun and air, will be apt to fail, and their quality at beſt will be inferior: they ought not however to be expoſed ſo as to have any part above ground. They ſhould not be deeper than four inches or four inches and a half in any ſoil; but in a dry warm one they need not be put in ſo ſhallow as in that which is ſtiffer and more retentive of wet [m]. Three inches is thought by many to be fully ſufficient, and if rains ſhould waſh the earth from them, it will afterwards be hoed up to the ſtems in courſe. The rooks ſhould be well looked after, for they will frequently find out the ſets, and make great depredation on the crop [n]. Field mice alſo ſometimes do much damage. Though earthing up be a very uſeful proceſs, yet that may be carried too far, if the ſets ſhould thus be buried too deep [o].

The cheapeſt and moſt expeditious method of planting, is by two ploughs following each other, the horſes not going in the furrow, and waiting at the ends till the ſets are dropped in. Four women and four children are ſufficient to drop after the two ploughs, which, as they return, of courſe cover the ſets, and leave a freſh furrow open for the next row. By this method two acres and a half may be planted in a day at the expenſe of 11s. 6d. an acre. A proper opportunity, after planting, ſhould be taken, to draw a harrow over the ground [p].

If the ground be moiſt, ſtrong or heavy, it ſhould be thrown into ridges of four or five feet each, and the ſets planted on the top of the ridges. The depth of the furrows alſo ſhould in this caſe not be more than three or four inches at the moſt; but in a very light dry ſoil, they may be five inches deep [q].

Early Potatoes, in Lancaſhire are generally planted in beds, in rows about eight inches diſtant, and the ſets four or five inches ſeparate, becauſe early Potatoes, being of a leſs ſize, require a ſmaller ſpace; but the advanced price theſe early crops obtain at market, render them a profitable article to the cultivator; who, beſides his profit from the Potatoes, has his ground prepared for another crop the ſame ſeaſon. This is ſometimes Turneps ſucceeded by Wheat. Or early Potatoes for ſets are planted; which, being got up in november, are immediately cut up into ſets, and preſerved in oat-ſhells (vulgarly called meal-ſhudes) or ſawduſt; where they remain till march, when they are planted, after having had one ſpit taken off, and planted with another, of a length ſufficient to appear above ground in the ſpace of a week.

But the moſt approved method is, to cut the ſets, and put them on a room-floor, where a ſtrong current of air can be introduced at pleaſure, the ſets laid thinner, namely about two lays in depth, and covered with the like materials, about two inches thick: this ſcreens them from winter froſts, and keeps them moderately warm, cauſing them to vegetate; but at the ſame time admits air to ſtrengthen them and harden their ſhoots; the doors and windows ſhould be opened in mild weather; they ſhould be frequently examined, and when the ſhoots are ſprung an inch and half or two inches, one half of their covering ſhould be carefully removed with a wooden rake or with the hands, taking care not to diſturb or break the ſhoots. Light is requiſite as well as air, to ſtrengthen the ſhoots; on which account a greenhouſe has the advantage of a room, but a room anſwers very well with a good window or two in it, and if to the ſun ſtill better. In this manner they remain till the planting ſeaſon, having all the air poſſible given them, when it can be done with ſafety from froſt. By this method the ſhoots at the top become green, leaves ſpring out, and they are moderately hardy. They are then planted in rows by a ſetting ſtick, the holes being carefully raked up; and thus they are enabled to bear a little froſt without injury. The earlieſt Potato is the ſuperfine white Kidney, from which four crops have been raiſed on the ſame ground; having ſets from the repoſitory ready to put in as ſoon as the others are taken up. A fifth crop is ſometimes raiſed on the ſame land the ſame year, of tranſplanted winter Lettuce. The firſt crop muſt have a covering in froſty nights [r].

In Cheſhire they alſo practiſe raiſing early Potatoes and having two crops; keeping ſets of the earlieſt ſorts in a warm place, where they may ſprout at leaſt three inches by the beginning of march, covering them with ſtraw or ruſhes in froſty nights. They plant them carefully with the ſprouts on, in drills, on a light ſoil, the end of the ſprout being juſt under the ſurface. Theſe yield a crop in the middle of may [s]. The ſame practice is followed in Cornwall, and ſometimes in the neighbourhood of London. But no good farmer, will take two ſucceſſive crops of Potatoes off the ſame ground in one ſeaſon.

Sets.

Mr. Miller is decidedly for planting large Potatoes entire; but he has had few followers. There is no doubt but that a good crop of fine roots may be obtained this way, in good ground, if ſufficient room be given them: but a much greater quantity will be produced from large pieces judiciouſly cut. Mr. Billingſley, the agricultural reporter for Somerſetſhire, affirms that whole Potatoes have been tried, and found not to anſwer. He recommends, as many others do, and ſeemingly with good reaſon, large cuttings from the biggeſt and fineſt Potatoes.

Robert Beatſon, Eſq. of Kilrie in Fifeſhire, took one of the largeſt Potatoes he could get, and planted it whole in his garden without dung, the produce was ſeventy-two bulbs, above twenty nearly as large as the original; the remainder of different ſizes, gradually decreaſing to about the ſize of a Walnut. Next ſeaſon he planted the whole of the produce alſo uncut, ſetting the largeſt in the front row, the next largeſt in the ſecond, and ſo on. He found not only that the ſtems of the largeſt bulbs were by far the ſtrongeſt, but that their produce alſo was much the greateſt; none of them producing bulbs larger than their reſpective original. Whether the Potato would have produced more if it had been cut into ſets, this experiment does not attempt to aſcertain, but Mr. Beatſon obſerves, that unleſs it would have produced a great deal more when cut, the advantages are in favour of ſetting them whole, by ſaving much labour, and occupying a leſs ſpace of ground. The largeſt Potatoes being often found neareſt the ſurface, he propoſes a quere, whether if theſe were taken away with-

out injuring the ſtems, five or ſix weeks before the time of raiſing the whole crop, the ſmaller ones would not grow to a much larger ſize? Since theſe experiments, Mr. Beatſon has always planted his Potatoes whole [t].

The Rev. Mr. Higſon, vicar of Bath Eaſton, planted, on the ſame day, and in the ſame ground, whole Potatoes in ranks, at the diſtance of three feet ſquare, and cuts of the ſame kind at eighteen inches ſquare. The four years following he planted whole Potatoes at the diſtance of two feet and a half ſquare, and cuts at eighteen inches. The whole ſets were earthed up three or four times, that is, as long as the haulm would ſtand, and a few ranks of the cuts were earthed up alſo. The whole ſets always produced a greater crop than the cuts, in proportion to the quantity of ground; and the Potatoes were larger and fairer. There was little or no difference in the produce of the cuts, whether the ranks be earthed up or not [u].

The experiments of Mr. Joſeph Wimpey turn out clearly in favour of cuts. He ſelected the largeſt and fineſt Potatoes, one half of which he planted whole, the other half was cut into pieces of a moderate ſize. The acreable produce was rather in favour of the latter; but then it is alſo to be conſidered that theſe alſo will plant nearly four times the ground that the whole ſets do, which is a conſideration in planting on a large ſcale, or when Potatoes are dear, as they often are in the ſpring [x].

Dr. Anderſon's experiments tend to prove that the produce depends greatly upon the ſize of the ſets. By varying the weight of them from two ounces downwards, he found that the produce from the ſame number of ſets of the largeſt was ten times the amount in weight of that from the ſmalleſt ſets. The latter indeed may be planted cloſer, and therefore the difference will not be ſo great: but then it is more difficult and expenſive to cultivate a field where the plants are cloſe, and the bulbs being much ſmaller, are leſs valuable weight for weight. There can be no doubt but that the ſame ground, with the ſame manure and culture, will yield a crop of at leaſt double the amount, with ſets not under two ounces, that it will with very ſmall ones. Dr. Anderſon therefore condemns the uſe of thin ſlices from the ſurface; and ſtill more the practice of planting ſhoots without any part of the bulb [y].

Experience proves, ſays Mr. King, that the beſt cuttings or ſets is to be had from the largeſt Potatoes. Small ones have nearly as many eyes as large ones of the ſame ſort. But a good ſet, part of a large Potato, all other things equal, will produce a ſtronger and better plant than part of a ſmall Potato. Each eye ſhould be cut out by two cuts of a ſharp knife: which leaves the ſets ſtronger than is generally done by the common way of cutting, or rather ſlicing off the ſet with one cut of the knife; and many more ſets will be obtained. If the Potatoes be large, there will ſtill remain, after the ſets are taken out, ten or twelve ſtones weight out of twenty; which may be profitably uſed for pigs, cows or horſes. No part ſhould be cut, which has not a very apparent eye in it; nor is the ſtalk end proper for ſets [z]: or indeed either end, called by ſome the noſe and tail.

It has been remarked by ſome farmers, that there are two kinds of eyes in every Potato, the one prolific, the other not; the former ſunk deep in the bulb, and producing a ſtrong vigorous ſhoot; the latter not ſinking ſo deep, and always having a little ſwelling in the middle, from which a few weak ſhoots ſpring forth, that even in favourable circumſtances yield but a ſcanty crop in compariſon with the former. This remark yet requires to be aſcertained by experiment [a].

Mr. Billingſley recommends the uſe of large ſets, picking out the fineſt Potatoes for this purpoſe, and ſlicing them in half from the crown to the root. His trials have all led him to prefer ſuch ſets to whole ones [b]: but his method of ſlicing them is thought by ſome to be the worſt method of any.

The ſets ſhould lie ſome time before they are planted, otherwiſe they will be apt to rot. But if they be thrown into a heap, they will heat, by which if they are not deſtroyed they will be weakened, and, in the opinion of ſome, produce the curl and a poor crop.

Mr. Hollins adviſes, that in cutting Potatoes for ſets, care ſhould be taken not to cut them entirely through, but when the knife has penetrated about half way, the other half ſhould be broken off. This operation will ſhow whether the Potato has proper vegetative power or not; if the knife enters eaſily, and the Potato breaks off ſoft, then it is fit for a ſet; but if the knife enters with ſome difficulty, and the Potato breaks off harſh and rough, though it may not appear to want ſap, it will remain whole in the ground, or produce curled leaves [c].

Mr. William Payne thinks the common mode of cutting for ſets, a moſt improvident and thoughtleſs waſte. Inſtead of cutting away the whole, no more than is neceſſary for extracting the eye needs to be taken; and thus the conſumption for ſets will be comparatively trifling: for out of three or four ſacks of Potatoes, the eyes judiciouſly cut, generally amounting to leſs than two buſhels, would be quite ſufficient for planting an acre, and would of courſe leave the reſt of the root for uſe. Mr. Payne has proved this mode for many years, with as good crops as others [d]. It was not uncommonly practiſed in the late years of ſcarcity; and the eyes were taken out with a little iron ſcoop, ſuch as cooks uſe for taking out ſmall pieces of carrot and turnep for their haricoes. But this mode being inconſiſtent with the reſult of Dr. Anderſon's experiments, comparative trials ſhould be made, before we can come to a ſatisfactory deciſion.

Potatoes may be raiſed from the parings, cut thick, as Turneps generally are for the table; and thus about two thirds of the ſubſtance may be left for eating. Mr. John Wagſtaffe, of Norwich, planted, about eighteen inches aſunder, ten whole Potatoes, about the ſize of turkey eggs; and at an equal diſtance, parings of about fourteen, from ſomewhat larger roots. The produce was, from the ten whole Potatoes 29lb. 4oz.: and from the parings 29lb. 12oz. Two of the largeſt, weighing together 31oz. aroſe from the parings: the two largeſt from the whole ones weighed 25oz. [e]

Potatoes may alſo be raiſed from the ſhoots, which are commonly produced in the ſpring, fall off in moving or cutting, and are commonly thrown away. The Rev. Dr. Maunſell has given the following directions for their culture.—In the month of march open the heaps of Potatoes, and if the ſhoots be ſufficiently ſtrong, that is, about ſix inches long and in a healthy vivid ſtate, let them be carefully picked off, and given to children of about ten years old to plant in drills, ſeven or eight inches aſunder, with the root downward; put a ſmall quantity of dung upon each ſhoot, and then cover them lightly with earth, to keep out any ſlight froſt; when the ſhoots throw out their leaves, and are about four inches above ground, give them a covering, leaving about two inches of the green ſtock above ground, and as they proceed in growth, let them be covered as before, till the earth between the ridges raiſes the drill at leaſt twelve or fourteen inches high. If there be occaſion to open the heaps before the time of planting, the ſhoots, taken off with care, laid in ſmall bundles, and covered with earth, will remain in a vegetative ſtate for a month. The Potato in the mean while is left entire for the ſuſtenance of man or cattle [f].

Six acres and thirteen rods of land were thus planted at Petworth in Suſſex with good ſucceſs. Drills were drawn, and children dropped the ſhoots horizontally into the drills, ſo as to touch each other at both ends; a man then covered them with a hoe. The ſhoots were from one foot to a foot and half in length.

The

Digitized by Google

The plants ſhot up from every joint, ſo that ten or more ſprang from one ſhoot, but the longeſt ſucceeded the beſt. They were earthed up three times in the courſe of the ſummer. The weeds, which were numerous, were pulled up and laid between the rows, and where moſt weeds were laid the plants were ſtrongeſt, and the produce greateſt, owing to the putrefaction of the vegetables, which afforded nouriſhment to the plants, and kept them moiſt. A buſhel of ſhoots having been thrown into a hole filled with dead leaves and the mowings of turf, two months after were found to be alive and in a forward ſtate of vegetation: this fortunate accident gave occaſion to preſerve the ſhoots afterwards, by putting them into a hole, and covering them with mould [g].

Mr. Lockett, of Donnington near Newbury, put three Potatoes, on the 17th of December, into a ſmall caſk, placed in a cellar: the 10th of march he took off fifteen ſhoots from them, and ſet them with a dibbler, about one foot ſquare: the 16th of april he took twenty-one ſhoots more from the ſame Potatoes, and planted them as before: on the 22d of may he again took twenty-five ſhoots, and planted them alſo: he then waſhed and boiled the three Potatoes, which proved very good to eat. From theſe ſixty-one ſhoots he had as many Potatoes as weighed 92 lb. though the rooks did him much damage.

After a mild winter, about the month of may, he goes over the fields where Potatoes had been planted the preceding year, and pulls up from among the corn all the ſhoots produced by the Potatoes which had eſcaped the diggers; and theſe ſhoots he plants in the ſame manner as directed above [h].

On the 18th of may, 1772, Mr. Ellery near Manchester, tranſplanted a number of ſprouts into an Onion bed that had failed, about a foot and half aſunder. In october they were taken up, and for ſize, quantity and quality, exceeded all he ever had in the common way.

On the 2d of january in the ſame year, Mr. Kirk, of Wilderſpool, near Manchester, having made a hot-bed for Potatoes, about forty of the ſets being left were hung up in a kitchen, and there remained unnoticed till about the 25th of april; when obſerving the baſket, and perceiving ſomething green on the edge of it, he took it down, and found that the Potatoes had ſprouted half a yard in length, and that many very ſmall bulbs were formed on the fibrous roots which had grown out. He planted them in his garden, in a rich ſandy ſoil without manure; putting the roots into the ground three inches deep, and laying down the ſtems horizontally, covering them with two inches of ſoil, and leaving the tops uncovered. He found that theſe produced larger Potatoes than the roots in the hot-bed. He took them all up, and picked off the large bulbs, which amounted to from four to twelve on each root; and then he ſet the roots again on the ſame ground. This he has ſucceſsfully practiſed for many years, ſometimes even twice, and has had a third crop at michaelmas. When this method is tried, the roots muſt be watered on the evenings of hot days.

In january the year following he made a ſecond trial with a larger quantity; by placing many Potatoes of early ſorts on a thick layer of gravelly ſoil cloſe to each other, over an oven, ſlated over, but open to the ſouth-weſt, and covering them two inches deep with the ſame earth. At the end of april he took them up, and found the ſtems a foot long or more. He was very careful both in taking them up and planting them, not to injure the delicate fibres. He manured them, but in all other reſpects treated them in the manner above deſcribed, many of the fibrous roots having then Potatoes formed upon them, nearly as large as walnuts. By one ſharp night's uncommon froſt, they were nearly deſtroyed. However freſh ſtems grew up in a few days, and he gathered from them on the 3d of june, finer Potatoes than were ſold at that time in Manchester from 1s. to 1s. 6d. the lb. being the produce of hot-beds.

[g] Young's ann. 28. 324. [h] Tranſ. Arts, 13. 207.

After taking off the larger Potatoes, he planted the roots for a ſecond crop, and in ſeptember obtained a very large produce. He weighed the increaſe of many ſeparate roots, from 4 lb. 8 oz. to 14 lb. 12 oz. the Potatoes being the largeſt of the forward ſorts he ever ſaw [i].

Quantity.

The quantity of Potato ſets required to plant an acre has not been well aſcertained: it muſt depend much on the ſize of the cuttings, and the diſtance at which they are planted. On a compariſon between whole Potatoes and cuttings, Mr. Joſeph Wimpey aſcertained that thirty-ſeven buſhels and a half of the former, and twenty buſhels and a half of the latter, were required to plant an acre. In different diſtricts of England I find the quantity varying from fifteen to thirty buſhels.

In the North Riding of Yorkſhire	15	buſhels
In Suffolk	15 or 16	——
In Durham	16	——
In Suſſex	18	——
In the Iſle of Man	18 to 20	——
Dr. Wilkinſon at Enfield	20	——
In Eſſex	24	——
In Kent	18 to 30	——
In Lincolnſhire	30	——
In Wiltſhire	4½ to 6	ſacks
In Somerſetſhire	5 to 8	—— } 240 lb.
In Nottinghamſhire	7	—— } each.
Mr. Billingſley	8	—— }

The ſacks are probably three buſhels each.

In Scotland they reckon chiefly by bolls. In Roxburgh and Tweedale they plant two bolls. In Argyll, two bolls, making ten barrels. In Fife, three bolls to a Scotch acre. In Galloway, 11 cwt.

In Ireland, they reckon by barrels, which meaſure differs in different diſtricts: and accordingly the quantity directed for ſetting an Iriſh acre varies from four to nine barrels. I find the following:—4 barrels each 6 cwt.—4 barrels each 64 ſtones.—4 barrels, each 5½ cwt.—6 barrels, of 48 ſtone—8 barrels of 20 ſtones.—9 barrels.—14 barrels, each 20 ſtones.—12 pecks, each 56 lb.—10 buſhels of 3 cwt. each.—30 to 40 buſhels.

To form ſome judgment of the above quantities, it is neceſſary to remark, that an

Iriſh plantation acre and an half equal 2 acres Engliſh.
Cunningham acre to the Engliſh nearly as 15 to 13.
Corniſh acre equal 1⅓ ſtatute acre Engliſh.
Iriſh Barrel equals 4 buſhels Engliſh or 32 ſtones.
—— —— near Dublin, equal 20 ſtones or 280 lb. or 4 Engliſh buſhels.
—— —— at Weſtport, 12 cwt. or 16½ pecks.
—— —— at Ballyſhannon, 10 peck, each 5ſt. 4 lb.—In the country they give 6 ſtones.
Briſtol Barrel, contains 4 buſhels heaped, weighing 22 ſtones; or 6 buſhels ſtrike meaſure, weighing 15 ſtones each.
Scotch Boll equals 16 pecks, each weighing 24 lb. avoirdupois, or 384 lb.
—— —— Teviot, equals 30 ſtones, or 420 lb.
—— —— Fife, 24 Dutch ſtones. The barley firlot uſed for meaſuring, half heaped or as many as can be laid on with a ſhovel.
—— —— Roxburgh, $\frac{25}{100}$ larger than the ſtandard: equal 7 buſhels, 3 pecks, 11 pints and a fraction Engliſh ſtandard meaſure.
Engliſh Buſhel, heaped, weighs from 70 to 75 lb. In Lancaſhire, 90 lb.
—— Sack or Bag, holds 3 buſhels heaped, weighing 240 lb.

Diſtances.

The beſt diſtance at which the rows of Potatoes may be placed has by no means been aſcertained, and practical men have differed much on the ſubject: it muſt after all be governed in ſome degree by circumſtances, ſuch as the quality of the ſoil, the quantity of manure laid on, the ſort of Potato intended to be cultivated, the method of management, whether by the horſe-hoe or by common hoeing, &c. We find

[i] Hunter's Eſſays, 408, 412.

Digitized by Google

directions given for diſtances of rows, varying from eight inches to ſix feet: thirty inches is very commonly preſcribed, and is much practiſed both in our northern counties and in Scotland. For horſe-hoeing three and even four feet are good diſtances. Mr. Mayo, of Battel in Suſſex, prefers three feet to four; Mr. Haſſel on the contrary thinks four feet better than three. Circumſtances may induce a preference to four feet, but three is ſufficient for the horſe-hoe to work in, and is adopted by the beſt practitioners. Mr. Young commenced with wider intervals; but had greater crops when he adopted ſuch as were narrower. Dr. Anderſon has very well remarked, that ſome Potatoes ſend their bulbs downwards to a conſiderable depth, whilſt others puſh them upwards ſo as to be in danger of coming above ground: ſome again puſh out their fibres very far, and produce bulbs only at a diſtance from the ſtem, whilſt others produce the whole in a cloſe cluſter at the bottom of the ſtem [k]. It is evident that theſe different varieties require a different ſoil, culture and management, and that it would be abſurd to plant the third and fourth at the ſame diſtances.

The following are the intervals between the rows of Potato ſets adopted in ſeveral diſtricts and by different practitioners:

8 inches; and 6 inches from ſet to ſet: by Dr. Wilkinſon, of Enfield.
12 inches; in the Iſle of Wight.
12 to 15 inches; in Suffolk.
15 inches; with ſets 9 inches aſunder: Sunderland.
18 inches to 4 feet; ſets 9 to 12 inches aſunder: in Mid Lothian.
18 or 20 inches, with ſets 12 inches aſunder: or, 30 inches, or 3 feet; with ſets 8 or 10 inches aſunder. County of Fife. The narrow intervals by labourers; the wide by farmers.
20 inches, and 10 in the rows. Kent.
24 inches. Suffolk.
24 to 30 inches, and 10 or 12 inches in the rows. Weſt Lothian.
24 to 36 inches; 12 inches in the rows, Durham: 10 inches, Iſle of Man: 8 inches, Selkirkſhire.
30 to 33. Clydeſdale.
32 to 40; 12 inches in the rows. Northumberland.
3 feet; Lancaſhire, Berwickſhire, Dumbartonſhire; 9 or 12 inches in the rows: Lancaſhire.
3 to 4 feet. Elgin.
4 feet. Wiltſhire and Ayrſhire: 6 inches in the rows, in Wilts.
5 or 6 feet. Herefordſhire.
Every third furrow; and 4 inches aſunder in the rows. Nottinghamſhire.
One bout ridges; and 10 inches aſunder in the rows. North Riding of Yorkſhire.

Theſe diſtances are moſtly taken from the Agricultural Reports, and doubtleſs vary occaſionally in the ſame county or diſtrict, in the practice of perſons more or leſs enlightened.

Times.

The practice under this head varies extremely, from the middle of march to the beginning or even middle of june. April however is the moſt uſual month for planting the common ſorts of Potatoes for the general crop; and that is the prime ſeaſon for it in Lancaſhire. In order to have them come early, they are planted in march, january, and even october. But theſe are in hot-beds. Early planting may ſucceed when the ſpring froſts do not happen to be ſevere; but that being ſeldom the caſe, it is hardly prudent to riſk very early planting for the main crop. Froſts however often happen in may, and ſometimes in june, which injure the crop more or leſs; but theſe ſeldom deſtroy it, and cannot be avoided. In the ſeaſon for planting, the ſort of Potato, the ſoil and ſituation, and the quantity and quality of manure are to be conſidered.

In Lancaſhire, april is the prime ſeaſon for producing a crop of good Potatoes for the table, becauſe this vegetable requires a certain portion of time, to acquire that degree of maturity, which renders it peculiarly mellow and farinaceous; yet it is frequently planted as late as may or even june, and yet produces abundant crops, but not of the ſame matured quality, as thoſe planted at a more early ſeaſon.

The apprehenſion of froſts ſometimes operates againſt planting at an early ſeaſon; yet good planters riſque the chance of froſts in order to obtain ſuperior quality [l].

The following times, among many others, have been regiſtered:

March to the firſt week in may. Kent.
March, at the end, or beginning of april. Ireland: but
April, the middle, to the middle of may is moſt common; and more are planted after the firſt of may than before it.
April, the firſt or ſecond week; found to be moſt advantageous, by the Rev. Mr. Cloſe, of Trimley in Suffolk.
April, the two laſt weeks. Roxburgh.
April or beginning of may. Perth.
April, the end, or beginning of may. Middleſex and Cheſhire. Argyll.
April, the middle, to the middle of may, ſometimes beginning of june. Fife and Clydeſdale.
April, the end, and all may. North Riding of Yorkſhire.
April and may. Somerſetſhire.
April to june the firſt. Mid-Lothian.
May, the beginning: the beſt time on a large ſcale. *Bath papers*, 2. 357.
May the 22d planting at Sandy in Bedfordſhire.
May to the end; though the ſooner they are planted the better.
June the beginning; (*Bath papers*, 2. 356.) and middle. Suffolk. (*Young's annals, vol.* 23. *p.* 32.)

For early Potatoes, they plant ſometimes in october; and if any ſevere froſt ſhould come without ſnow, they are covered with peas-haulm, bean-ſtalks, ſtraw, or other light covering. The crop is dug up in april or may; and another immediately put in, which is taken up in october [m].

For Potatoes raiſed in hot-beds, the ſets are put in about Chriſtmas, or in january. Theſe come to market in april, may and june.

PRODUCE.

The general produce that may be expected from an Engliſh ſtatute acre, in a ſoil adapted to Potatoes, and properly managed, is from 300 to 400 buſhels. Some perſons have produced more under peculiar circumſtances; as far as 700, and even 1080 buſhels; but no prudent man will reckon upon ſuch extraordinary crops. No ſatisfactory average can be drawn, unleſs crops were ſelected and claſſed, according to ſoil, management, &c. I find averages regiſtered from 240 to 480 buſhels. Mr. Young ſtruck an average of eleven years experiments on the Cluſter Potato, of 332 buſhels on an acre. From forty caſes ſelected from the Agricultural Reports, Young's Annals, the Bath Papers, &c. I found an average of 384½ buſhels. And ſelecting inſtances from the Report of the Committee of Agriculture, twenty in a claſs, I obtained the four following reſults—361. 365. 290. 400. which, taken together, give an average of 354 buſhels. Theſe three averages again give a general average of 357 buſhels nearly.

Mr. Henry Harper, of Bank-Hall in Kirkdale, Lancaſhire, gets 240 buſhels of Scotch and Pink-eye Potatoes on a ſtatute acre of old arable; and 320 buſhels of the Ox-noble or Cluſter: the buſhel weighing 90 lb. On freſh land, from which a crop of Oats was taken, he had 320 buſhels of the former, and 480 of the latter [n].

Mr. Lodge, of Great Blakenham in Suffolk, has from 360 to 525 buſhels (weighing 66 lb. each) of Ox-nobles, on an acre [o].

In the Lancaſhire Report it is ſaid, that the produce of a ſtatute acre, on a medium, is from 200 to 300 buſhels, but then the buſhel weighs 90 lb.

[k] Comm. Agr. app. p. 112.
[l] Report, 58.

[o] Young's annals, n. 198. p. 200.

Digitized by Google

The average crop in Lincolnſhire is ſaid to be 480 buſhels, each weighing 80 lb. and yet 330 buſhels of Ox-nobles on an acre is called an extraordinary crop; and 70 ſacks or 210 buſhels, a middling one. On warp land they get 100 ſacks or 300 buſhels; and in Axholm, on new land, 80 ſacks or 240 buſhels on an acre [p].

In the Midland, according to Mr. Marſhall, 300 to 400 buſhels is reckoned a fair good crop; but he has no reaſon to doubt of 600 buſhels an acre having been produced in two or three inſtances.

Mr. Bucke, of Worlington in Suffolk grew 432 buſhels to the acre of the Dutch upright and Pink-noſe ſorts; and the year following 628 buſhels of Champions [q].

In the North Riding of Yorkſhire, from 200 to 300 buſhels an acre, of the table ſorts, are eſteemed a good crop: thoſe cultivated for cattle, will generally produce more by 50 or 100 buſhels on an acre [r].

The Rev. H. J. Cloſe, of Trimley in Suffolk, ſays that on land well managed, the ſets 15 ſquare inches from each other, 15 buſhels to the acre; the produce, on a good mixed loamy ſoil, will amount to 300 buſhels [s].

Sir Thomas Beevor had 346 buſhels to the acre of the White Champion; 648 of a ſort from Mancheſter; and after the rate of 1080, of a new ſort from Liverpool, lately raiſed from ſeed [t].

From 8 to 15 tons is reckoned a crop in Eſſex; 10 tons, 126 lb. to the hundred has been a crop aſcertained there. Twenty-five tons or 275 ſacks of the Red Cluſter have been obtained, but that was in an old hop-yard, well dunged [u].

In Scotland from 30 to 40 bolls is a common crop. Thirty is in ſome parts accounted a large average: in others 40, on a Scotch acre. In Fife they have from 50 to 70; but the average is ſuppoſed to be 40 bolls. In Clydeſdale upwards of 24 tons have been taken on an acre; but the produce is frequently below half that quantity [x]. In Perth, Sir William Stirling, of Ardoch has often raiſed 40 bolls on an acre of light moor [y]. In Roxburghſhire the average return is from 36 to 40 bolls on an acre: and their boll is ſomewhat larger than the ſtandard boll of Scotland.

In Ireland they expect 300, or from 300 to 400 buſhels. They commonly reckon by barrels; which, in general, contain 4 buſhels. In different parts of Young's Iriſh tour we have from 28 to 120 barrels aſſigned as the produce of an acre: 100 to 120 barrels is ſaid to be a middling produce; and we have two averages of 64 and 82. The following crops, among others, are regiſtered.

80	Barrels	at	32	ſtones.
60	——	—	20	ſt.
40	——	—	64	ſt.
60	——	—	21	ſt.
50	——	—	5½	cwt.
26	——	—	10	cwt.
50	——	—	48	ſt.
50	——	—	18	ſt.
40	to 80	—	20	ſt.
108	——	—	252	lb.
100	——	—	20	ſt.
120	——	—	20	ſtones; of the Cluſter.
28	——	—	16	pecks; 60lb. to the p[k].
80	to 100	Briſtol barrels.		
144	to 249	pecks, of 56 lb.		

It ſhould be recollected that the Iriſh acre is bigger than the Engliſh.

The produce of a ſingle Potato is very great, if all the advantages of garden culture be given it. One Cluſter Potato cut into 24 pieces produced 165 lb. One Howard Potato cut into 4 ſets, yielded 90 bulbs, meaſuring 2 pecks, and weighing 31 lb. [z] One Potato from Quebec produced 132 bulbs, weighing 39 lb.

A large Potato cut into 9 pieces, planted in a garden with dung, by earthing up and laying the ſhoots, produced 575 ſizeable bulbs, which weighed 8 ſt. 8 lb. And a large white Potato, cut into 17 ſets, and planted in hillocks, at 4 feet diſtance, produced 10 pecks of ſizeable Potatoes.

Single Potatoes are alſo ſometimes of an extraordinary ſize and weight. One of the variety called the Golden Dab, meaſured 9½ inches long, 8 inches broad, and 2 feet in circumference: the weight was 8½ lb. averdupoiſe. Another weighed a pound heavier [a]. Sir William Fordyce ſent a Potato weighing 8 lb. 6 oz. to the emperor Joſeph.

An eſtimate of the produce that may be expected from an acre of Potatoes is imperfect, unleſs we take into conſideration the expenſe of growing them, and the value when grown, either as an article for the market, or for home conſumption.

The expenſes vary much with circumſtances, but with good management ought not to exceed 10l. Three hundred buſhels at 1s. 3d. which may be conſidered as a middle crop, and a middle ſelling price, is 18l. 15s.; even at 1s. it is 15l.; conſequently here is a profit of from 5l. to 8l. 15s. on an acre.

In Eſſex the expenſes run very high, even to 15l. 11s. or upwards of 30s. a ton, ſuppoſing the crop to be 10 tons; if they are ſold at 40s. the ton, which is the loweſt price at the London market, this leaves a profit of near 5l. But the price is frequently double [b].

The Rev. Mr. Cloſe's account of his crop is more advantageous:

Expenſes - -		7 6	8
Sold 20 ſacks (3 buſh.)	at 7s. 6d.	7 10	0
20 ——	at 9s.	9 0	0
24 ——	at 5s.	6 0	0
		22 10	0
Profit -		15 9	4 [c]

Mr. Wimpey ſtates the produce, expenſe and profit of two ſtatute acres thus:

Produce 750 buſhels, deducting 75 buſhels for tithe paid in kind, leaves 675, at 1s. the buſhel - - -		33 15	0
Expenſes - - -		13 7	3
Profit on 2 acres -		20 7	9
Profit on 1 acre -		10 3	10½ [d]

Mr. W. Pitt, of Pendeford.

Produce 300 buſhels (80lb. each) at 1s. - - - -		15 0	0
Expenſes - - - -		9 3	6
Profit -		5 16	6

Prime coſt 7d. ½ the buſhel.

Again:

Produce 225 buſhels, at 1s. -		11 5	0
Expenſes - - - -		6 11	9
Profit -		4 13	3

Prime coſt 7d.

The Rev. Mr. Abdy, on an acre of Woodland ſtubbed up.

Produce 563 buſhels, at 1s -		28 3	0
Expenſes - - - -		16 13	6
Profit -		11 9	6

Again, on half an acre near his houſe.

Produce 320 buſhels, at 1s. -		16 0	0

60 —— at 4s. 4d.	13	0	0	5	0	7	6	19	5
480 buſhels at 8d. -	16	0	0	9	8	8	6	11	4

They ſell commonly from 1s. to 1s. 8d. the hundred weight; and from 3s. 6d. to 8s. the barrel. The latter is a common price, and ſometimes it riſes as high as 12s.—One ſhilling and 1s. 6d. are common prices in England; ſometimes it falls as low as 8d. and in ſome parts is as high as 2s. or more. When Potatoes are cultivated in large quantities, they have frequently no ſale adequate to the expenſe, unleſs near a great town or in a very populous neighbourhood; they muſt then be applied to feeding ſtock, which ſeldom pays more than 8d., 10d. or 1s. a buſhel, and ſometimes nothing: but it is a good preparatory crop, and raiſes a great quantity of manure.

Taking Up.

Potatoes are raiſed or taken up in october, when the ſtalks are withered, either with the plough or the three-pronged fork. In large concerns they commonly uſe the common or double mould board plough without the coulter to ſplit the furrows, women and children following to gather them. In this method many of the roots will be left in the ground, unleſs a pair of harrows with long tines are drawn over, or men break the ground with forks after the plough, for the pickers; and there is danger of the plough not going deep enough to avoid cutting the roots, eſpecially in thoſe ſorts which ſtrike down. To leſſen the expenſe of this operation Mr. Young invented an iron ploughing harrow, to fix in the holes of his ſhim beam, with two, three or four teeth (according to the tenacity or friability of the land) ſtanding obliquely, ſo that the horſe walking in the path of the furrow, the teeth might be in the direction of the land turned over by the plough. But the labour to keep it in that direction being found on trial too great, he added a ſemicircular iron to ſlide againſt the land ſide of the furrow at the bottom. This harrow, with one man and one horſe, without any boy to lead, lays all the Potatoes bare, and does the work of ten or fifteen men. Firſt the plough goes, then the boys pick all the roots that appear; the harrow follows, and the boys pick again. By this tool, the expenſe of taking up was reduced more than one half[f].

[a] Young's Annals. [f] Tranſ. arts, 4. 72.

In gardens and in ſmall concerns the three-pronged or broad three-tined fork is more commonly uſed. This mode is alſo followed in Eſſex, at the price of three guineas an acre: and in the Midland diſtrict, where they pay from 1d. to 2d. a buſhel; and in many parts of Scotland.

The ſpade is much uſed in Ireland, and in ſome parts of England, where the lazy-bed method is adopted.

The time of taking up is from the end of ſeptember to the middle of november. In Ireland they are ſometimes even later than this. But the decay of the haulm or ſtalks is the beſt direction, for if taken up ſooner, they will not keep well, and after this there is no addition to the growth of the roots; but as ſome decay later than others, it is abſurd to preſcribe any particular week for the operation; only they ſhould be taken up before ſevere froſts ſet in, and if poſſible in dry weather. In Scotland it is neceſſary to attend to this circumſtance of froſt, but in the ſouthern and weſtern parts of England the autumnal froſts are rarely ſo ſevere as to freeze the roots in the ground, unleſs they are near the ſurface. If there ſhould not be leiſure to get up the whole of the crop, and froſt is expected, it may not be amiſs to leave the whole of the haulm over that part, inſtead of carting it to the fold-yard.

If many ſmall bulbs ſhould be left in the ground, as is ſometimes the caſe, they will be detrimental to the ſucceeding crop. The ground therefore ſhould be harrowed, and ſwine turned in to eat them up, or if Wheat is to be ſown immediately, the land ſhould have a clean ploughing or harrowing, by which few roots will eſcape, and the field is in the moſt perfect condition for the ſucceeding crop.

Preservation.

The common method of preſerving Potatoes through the winter is in heaps or pits, on dry ground, with a bed of ſtraw at the bottom, covered with ſtraw ſix or eight inches thick, and over that a cover of earth a foot thick, of that which is thrown out of the pit, or taken from a trench dug round the heap; well clapped down with a ſpade, and ſometimes a row of turf over all. If put up dry and in good condition, not in quantities too great, they may thus be preſerved through the moſt ſevere winter without injury; but they will ſhrink in meaſure about one ſack in twenty. The drier the ground, the deeper may be the trench; but if it be at all wet, either the heap ſhould be above ground, or a drain ſhould be made from it. If poſſible, the pit ſhould be on a declivity. Attention muſt be had that rats and other vermin do not burrow into the heaps or pits. If the Potatoes are not dry, they ſhould be carted to a barn or ſhed, where they ſhould be turned over, and the ſmall ones, with ſuch as are cut or otherwiſe injured, picked out, before they are pitted. It is not a bad precaution, to keep open holes through the mould to the ſtraw for ſome time, for the heaps will ferment more or leſs, according to their ſize and moiſture: when the fermentation has ceaſed, the holes ſhould be cloſed, to keep out froſt and wet. If the Potatoes are to be kept long, the heaps or pits ſhould be the leſs.

In Lincolnſhire and the northern counties theſe preſerving pits are called *Pyes*. In the Midland counties this method of laying them up is called *Camping*. They judiciouſly make their *camps* or pits ſhallow; not deep as ſome, or on the ſurface as others; the uſual depth is a foot. The pit ſhould be three, or at moſt four feet wide; and the length proportioned to the quantity: if this be very great, ſeveral ſhort ones are better than one very long. The Potatoes, on a bed of dry ſtraw, are ridged up, and then covered with long wheat ſtraw, laid evenly, like thatch; over this the mould out of the trench is ſpread, and the ſurface made firm and ſmooth with the back of the ſpade. A coat of coal aſhes is ſometimes ſpread over the mould, as a farther guard againſt froſt. Theſe camps are tapped at the end; ſome battins or a quantity of looſe ſtraw, being thruſt cloſe into the opened end, as a bung or ſafeguard[g].

[g] Marſhall's Midl. 1. 250.

Digitized by Google

Mr. Marſhall, in his Economy of Yorkſhire (2. 63.) ſuggeſts, as an eligible receptacle for Potatoes, a long arched vault, running endway into the ſide of a hill, or the ſide of a pit or other hollow, with a door at the end, level with the ground below; with a road over the top; and with one or more ſhooting holes, ſimilar to thoſe of coal-vaults under the ſtreets of towns.

General Murray, in Suſſex, dug holes in the ſide of a hill, ſix yards wide, and ten deep. He carted from the field and unloaded at top. He took them out at the end at bottom, which opened to the ſlope of the hill, where a wall was built with a door. When full, a ſtack of ſtubble or ſtraw was built over the hole, wide and large enough for ſecurity againſt all froſts. The effluvia of the roots riſing through the ſtubble, does not occaſion their rotting from heat [h].

In ſome places Potatoes are houſed in winter. In Canada, ſays Mr. Tooſey, we have admirable root-houſes to preſerve them in perfect ſoundneſs from october to june [i]: but he does not deſcribe them. In Scotland, they are very commonly preſerved in the houſe, where being liable to injury by heating or freezing, they ſhould be put in perfectly dry, and the walls muſt be lined with ſtraw or dry fern, and they ſhould be covered with ſtraw, mats, or ſacks, in froſty weather. If they cannot, on account of the ſeaſon, be houſed perfectly dry, it will be neceſſary to turn them over during the winter, and to pick out ſuch as are unſound. For this purpoſe there muſt be ſome ſpare room in the root houſe; which may be had by keeping a ſpace open in front, into which the Potatoes may be removed for ſorting. And if the repoſitory be divided into binns, the different kinds may be placed ſeparate, and the heaps will not be ſo large as to ferment readily [k]. I find a large three-ſtall ſtable, built of brick and well ceiled, to anſwer the purpoſe of ſuch a root-houſe very well. When they are kept in a common room, barn or outhouſe, dry ſand, ſaw-duſt or ſtraw is laid on the floor, the ſides are well ſtuffed with ſtraw, and they are covered with that or the chaff of oats: but in ſuch places they will freeze in very ſevere winters. In order to have them good till june, or till the ſeaſon for new Potatoes return, after being houſed dry, and kept ſo during winter, they muſt be laid on a clean cool floor in the ſpring, and frequently turned, to prevent their ſprouting. Near Liſmore in Waterford, they are kept on hurdles, raiſed high enough for the mould to fall off in turning them, which is often done. Moiſt warm places will not do. Cellars therefore are improper: a large wine vault has been tried, but found to be too warm, and they ſprouted.

Where land cannot be got in order for early planting, the Potatoes are cut up into ſets in november, and put on a room floor where a ſtrong current of air can be introduced at pleaſure, and covered with oat-ſhells or ſaw-duſt about two inches thick; this protects them from froſt, and by keeping them warm cauſes them to vegetate; the doors and windows are opened in mild weather; and when the ſhoots are ſprung an inch and half or two inches they remove one half of the covering with a wooden rake, or with the hands, taking care not to diſturb or break the ſhoots [l].

Disease and Cure.

The Potato is ſubject to a diſeaſe commonly called the Curl; and in ſome diſtricts, when it is thus infected, they ſay it is frizzled, or roſe-headed. Theſe names are given it from the obvious appearance of the leaves in this diſeaſe; but the deſtructive effect of it is upon the bulbs of the root, which become worſe and ſmaller in proportion to its influence.

A variety of cauſes is aſſigned for this diſeaſe, which was unknown till within forty years. Theſe are: 1. Diſtempered or vitiated ſets. 2. Forcing the plants from which the ſets are taken, by too much freſh dung, and earthing them up too deep, on land too rich, and in a ſouthern aſpect, and chooſing ſets from bulbs rendered large by this management. 3. Planting the ſame ſorts too long on the ſame land. 4. Taking the ſets from ſuch bulbs as have been heated or froſted in the heaps. 5. The firſt ſhoots being broken off before planting, by which means the ſets are weakened: 6. Planting too near the ſurface, and in old worn-out ground. 7. Planting indiſcriminately ſets of new ſorts raiſed from the ſeed. 8. Inſects attacking the ſets, or roots, or young ſhoots. 9. Unfavourable ſoils and ſeaſons.

One or more of the above cauſes may operate in producing this diſeaſe; and any or all of them in different circumſtances. He muſt be a careleſs cultivator indeed who will plant diſtempered or vitiated ſets; and he merits a bad crop, who ſells or eats all his beſt Potatoes, and plants the worſt. Yet Mr. Billingſley, a great farmer, and grower of this vegetable, planted whole Potatoes, large cuttings, ſmall cuttings, nay the mere eye only, but never could ſee any difference in reſpect to the curl. If the Potato was diſpoſed to be curled, it proved almoſt equally ſo in all methods; on the other hand, he never knew a true Dumfries Potato come curled the firſt year; perhaps the ſecond year a few would be curled; but beware of the third; for be aſſured, let the ſoil or manure be ever ſo good, almoſt all will be curled the third year, if planted in the ſame ſoil and neighbourhood [m].

Dr. Anderſon remarks very properly, that ſome Potatoes affected with the curl, produce ſmaller bulbs than ſound ones; ſhould one man ſelect from the heap all the ſmall ones to plant, he would probably have moſt of the curled ones, and very few of the ſound: and ſhould another pick out from the ſame heap only the largeſt bulbs, he would perhaps have ſcarcely one curled plant [n].

Forcing Potatoes, by ſetting them late, in a rich ſoil, well manured, having a ſouthern aſpect, eſpecially if the ſummer be hot and dry; or covered with green fern or other litter before the plants appear, is found by a ſeries of experiments to produce the curl. The ſet will be exhauſted in feeding the plant; but ſhould the weather become moiſt and warm towards the end of ſummer, the plants, eſpecially if they ſhould be earthed, may then produce a plentiful crop of large Potatoes, which will be fit for eating, but being produced from the ſtalk, after the ſet was exhauſted, will be defective in vegetative power, and the plants from them will be curled. If they were covered, the rain rots the fern or litter, and enables it to penetrate as a manure to the roots: thus the plants are forced to a ſecond growth, and the ſets from theſe bulbs will produce curled plants. Large crops may be raiſed by earthing and manuring; but theſe are not fit for planting. A portion of ground ſhould therefore be allotted for raiſing ſets [o].

Planting repeatedly on the ſame land or the ſame ſort on ſimilar ſoils, is very unadviſeable, and contrary to general practice with other crops. Potatoes have been grown for ſeveral years together on the ſame ſpot in rich land with high manuring; and labourers frequently do this in their confined gardens. But unleſs the ſort be changed it is found frequently to produce the curl; and on a large ſcale they are ſeldom planted two years together on the ſame land.

Whether the curl be occaſioned, as ſome pretend, by being froſt-bitten before or after planting; or, as others, by being heated in the heaps; or not: no prudent man will uſe ſuch for ſets in planting. For they muſt be weakened, and produce an inferior crop, if not the curl.

If the Potatoes intended for ſets have been ſuffered to exhauſt themſelves by ſprouting, they are unfit for the purpoſe; for whatever tends to weaken the ſet, will operate to the diminution of the crop, and probably bring on the curl.

If Potatoes be planted too near the ſurface, or where the ſtaple is very ſhallow, they will be liable to froſt, and conſequently to curl, if that produces it. They will alſo want proper nouriſhment, and therefore be weak; now weakneſs, from whatever cauſe, probably

produces diſeaſe. Old worn-out land muſt needs be improper for the ſame reaſon: but who in his ſenſes would expect a ſound or efficient crop from ſuch land?

For a long time after the introduction of the Potato, men were contented with the common ſorts then in uſe; but afterwards ſome aimed at raiſing new ſorts from the fruit. This has been thought by ſome to have occaſioned the curl in the firſt inſtance. It is aſſerted, that when the Potato is raiſed from the ſeed, about one plant in thirty will be curled, and if propagated, will retain this quality [p]. Others alledge, that plants lately obtained from ſeed, are free from the curl: but Dr. Anderſon aſſures us, from his own obſervation, that a large field, planted with Potatoes the third year from ſeed, had more than half the plants curled; while another field near it, planted with ſets, never as far as we know, produced from ſeed in this country, had ſcarcely one curled plant in the whole. The Dr. informs us, that the curl was not known in Scotland till a very few years ago; when, there is great reaſon to believe, it was introduced by means of ſeed Potatoes imported from the ſouth: and that it is now much leſs frequent in the northern and remote parts, than in the ſouthern and more commercial diſtricts [q].—By ſeed-Potatoes, the Dr. probably means, thoſe which are uſed for ſets, which is the vulgar acceptation: but this is ſo ſtrange a perverſion of language, that I have invariably uſed the word *ſets* for the cuttings or pieces of the root which are ſet or planted, and confined the word *ſeed* to its proper ſignification, of the rudiment of the new vegetable contained in the fruit, which in the Potato is a berry, and not an apple, as it is commonly denominated.

Dr. Anderſon will not allow ſome of the cauſes aſſigned above to have operated in producing the curl. For inſtance, it has been ſuppoſed, ſays he, that nature, fated as it were by having long produced this plant in a climate not deemed congenial to it, had become ſo far exhauſted, as to occaſion this diſeaſe. But if ſo, the more northern parts of this iſland, where the climate is the moſt unfavourable, ſhould have been ſooneſt affected by it. It has been farther ſuppoſed, that if the bulbs be froſt-bitten before they are houſed, this diſeaſe is produced from them; but the curl is leaſt known in thoſe diſtricts where the Potatoes are moſt liable to this accident. It has been ſaid, that Potatoes which were taken up before they attained perfect maturity, infallibly become affected with this diſeaſe; but in ſome cold moſſy ſoils, and expoſed ſituations, where the Potatoes muſt often be taken up whilſt they are yet in a ſtate of vigorous vegetation, this diſeaſe is ſcarcely known.

Upon the whole the Dr. conjectures that the diſeaſe depends entirely on the nature of the ſet, and that the curl, like ſome hereditary diſeaſes among animals, if once introduced, vitiates the prolific ſtamina, and is perpetuated as long as the infected breed continues to produce others [r].

There is no doubt but that in ſome ſoils, particularly in freſh land, the bulbs of Potatoes are attacked by inſects, which by affecting the ſtalk, will produce the curl in the leaves. Charles Mordaunt, Eſq. looking over a field ſet with whole Potatoes, obſerved a plant with two ſtems, the one curled, the other perfect; on taking up the root, he found a hole at that end where the curled ſtem grew, from which an inſect of the millepedes kind, about an inch long, eſcaped. The gardener took up ſeveral more plants; and every curled plant had the hole, or neſt, or the inſect itſelf: ſeveral ſucceſſive examinations confirmed the matter. The inſect does not attack the cluſter, late or autumn Potatoes: but the early ſummer ones remain ſubject to its depredations [s].

On a dry ſoil, in a very dry ſeaſon, Potatoes are ſubject to the curl. On the contrary a very wet ſeaſon, in ſtrong retentive land, is very unfavourable to the growth of Potatoes, but I cannot ſay whether it occaſions the curl. Dr. Anderſon alledges that the ſoil or ſeaſon is not the occaſion of this diſeaſe: for ſeveral ridges in a field in his neighbourhood, planted with Potatoes obtained from one particular perſon were very much curled, whilſt the remainder of the field, planted with Potatoes of the ſame ſort, obtained from a different perſon, were not at all infeſted with the diſeaſe [t]. This proves that the ſoil and ſeaſon were not the occaſion of the curl in this caſe: but it does not follow, that they may not ſometimes operate as cauſes.

Mr. Marſhall adopts the idea that the old varieties, formerly in cultivation, dwindling in produce, till they were entirely worn out with diſeaſe, new varieties were introduced; and that the diſeaſe vaniſhed with the old ones. In confirmation of this, he obſerved in Rutlandſhire, in a large piece of Potatoes, two ſtripes, which were almoſt wholly curled, whilſt the reſt of the piece appeared to be free from the diſeaſe. Enquiring into the reaſon of this difference, he was told that the healthy plants were a new ſort called *Manleys*; and the diſeaſed ones red-noſed Kidneys, which was heretofore the prevailing ſort. The circumſtance of the old ſorts being now almoſt entirely cut off by the curl, renders it probable that the diſeaſe is incident to declining varieties of Potatoes, as the canker is to declining varieties of fruit [u].

Mr. William Pitt, of Pendeford in Staffordſhire is of the ſame opinion; that the curl is owing to a degeneracy in the ſet, or to the particular variety being worn out, by planting too long on the ſame ſort of land [x].

Not only copious dunging is thought by ſome to bring on the curl, but manuring well with lime, or aſhes either of coal or wood. On a deep loam limed, near three fourths of the crop were curled; whilſt a few drills adjoining, not limed, and planted with the ſame ſort of Potato, were entirely free from the diſtemper. The experiment was repeated the year after with the ſame reſult. The curl has been ſince obſerved to prevail moſt in the diſtricts where much lime or aſh-manure is uſed [y]. A moderate quantity however of lime made into a compoſt with earth has no bad effect, and will be of uſe in deſtroying the wire-worm and other inſects that attack the ſets.

The method of cure is pointed out by the cauſes of the diſeaſe. If it be owing to the ſoil, that ſhould be improved by ſufficient manuring and good management; or, if wholly unfit for Potatoes, ſhould be given up. If the diſorder be occaſioned by any defect or weakneſs in the ſets, ariſing from their having been heated, or frozen, or over-forced, or exhauſted by ſhooting, or from whatever other cauſe; care ſhould be taken to procure proper ſets, and to change the ſorts occaſionally. If the land be rich and warm, the crop ſhould not be over-earthed; if it be dry, poor and ſhallow, it ſhould be well earthed up. For the roots ſhould neither be parched with the ſun, nor too far removed from its influence. If very rich dung, by forcing them too much, brings on the curl; ſpread it over the field, and plough it in, rather than put it immediately over or under the ſets in the furrows, eſpecially as the latter mode is apt to make the Potatoes ſcabby. In a proper ſoil, with good management, planting in the beſt ſeaſon, and due attention to procure good ſorts in a ſound healthy condition; changing the land, or bringing this in with other crops in a regular rotation; changing alſo the ſorts which are intended for ſets, or planting ſome by themſelves for that purpoſe: the crop will not be infeſted in general with the curl; or if a few of the plants ſhould be curled, they muſt be carefully pulled out.

Great attention is paid in Lancaſhire to changing their ſets, in order to prevent the curl. If any of their favourite ſorts are infeſted with it, they ſend them to the moſs or moor-lands to be cured. It is held as a general opinion in Scotland and the northern counties that moſs or peat-earth prevents the curl.

Inſects are not very deſtructive enemies to this crop. A moderate dreſſing of lime is the beſt ſecurity againſt them. A copious manuring with freſh rank dung encourages them.

Very unfavourable ſoils had better be given up. Bad ſeaſons cannot be wholly guarded againſt, but damage ariſing from them may be moderated by attention and good management.

In the North Riding of Yorkſhire, in the dales of the Moorlands, they make uſe of ſets of their own growth, only endeavouring to plant them on a ſoil as different from that on which they grew, as they can; by this means they in a great meaſure avoid the curl: but in the lower parts, the ſets of the kinds for the table are procured either from the Moorlands or from Scotland, and it is found neceſſary to renew them every year, or at leaſt every ſecond year; for in the third they will be very generally curled. No other prevention is known there for this diſeaſe or degeneracy, than renewing the ſets, and changing the ſoil. The Ox-noble, Champions and red kinds are not liable to this diſorder *. We ſhall ſee hereafter, whether theſe and other varieties now ſaid not to curl, degenerate as well as many of the reſt.

In the Weſt Riding they procure their ſets of the red-noſe Kidney from the neighbourhood of Berwick: and until they adopted this plan of changing, they were much troubled with the curl *.

In Argyleſhire, they attribute their not having the curl, to their changing the ſets very often, and planting much of them in new moſſy ground. This ſhould be a ſtrong motive to the culture of ſuch waſte lands *.

Raising From Seed.

In Lancaſhire they have a great variety of early Potatoes; and great attention is paid to raiſing thoſe of the beſt qualities from the ſeeds of the berries, or as they call the fruit, the apples or orabs. It is well known that this is the only way of obtaining new varieties; ſome of which will be better, and others worſe than the parent plant. The former will of courſe be propagated, and the latter thrown away: thus real improvements will be made; and if it ſhould be found that old varieties degenerate in time, as is the caſe in many vegetables that are raiſed any way but by ſeed, it will be neceſſary to have recourſe to this method, now little followed, of raiſing Potatoes from ſeed.

Dr. Hunter's method of raiſing ſeedling Potatoes is as follows. Hang a bunch of the berries in a warm room during the winter, and in february ſeparate the ſeeds from the pulp, by waſhing the berries in water, and preſſing them with the fingers. Then dry the ſeeds upon paper. In april ſow theſe ſeeds in drills, in a bed well dug, and manured with rotten dung. When the plants are about an inch high draw a little earth up to them with a hoe, in order to lengthen their main roots. When they are about three inches high, dig them up with a ſpade, and ſeparate them carefully for planting out, in a piece of freſh ground well trenched, ſixteen inches apart. As they advance in growth earth them up once or twice, to lengthen the main root, and encourage the ſhoots under ground. By this management, the bulbs, in the courſe of one ſeaſon, will arrive at the ſize of hen's eggs, and the haulm will be as vigorous as if ſets had been planted. But what proves the luxuriancy in the moſt convincing manner is, that flowers and fruit are produced.

In Lancaſhire, they are always two, and ſometimes three years, in bringing their Potatoes raiſed from ſeed to full ſize. By tranſplanting them with wide diſtances, many of the bulbs will attain their full ſize in one ſeaſon.

Theſe ſeedlings produce bulbs of all the varieties, and ſometimes new ones. There does not ſeem to be any difference, whether the fruit be taken from a round or a kidney Potato. Seeds from a red Potato, that has flowered in the neighbourhood of a white one, will produce both red and white.

Potatoes, when propagated from ſets, after a number of years are found to decreaſe in bearing, and ſhould be brought back every fourteen years to their original. From a want of attention to this circumſtance, Potatoes are ſometimes ſo run out, as hardly to return treble produce. The farmer complains that his land is tired of them, but the true cauſe is the age of the ſets. The increaſe of Potatoes raiſed from ſeed is aſtoniſhing. They continue in vigour about fourteen years; after which the produce gradually declines [b].

Mr. Henry Dobby, of Yorkſhire, recommends the ſeeds to be ſown in the beginning of march or ſooner, on a hot-bed, in lines about nine inches aſunder, one-third of an inch deep, and very thin; to water between the lines frequently, and when the plants are riſen a little height, to introduce fine rich earth between the lines, to ſtrengthen them; to admit air frequently, and before they are tranſplanted to water them plentifully, to make them riſe with a large ball of earth to their roots; old rotten horſe-dung and yellow moſs are the beſt manures; plant them in trenches, like Celery, with a ſpace of four feet between the trenches, and twelve or fourteen inches between each plant; as they grow up draw the earth to the ſtalks, but do not cover the tops. When the ground is brought to a level, dig it, and earth up the plants till pretty deep trenches are formed between the lines. With this treatment they will produce the firſt ſeaſon from a pound to five pounds weight on a plant; and many conſiderably more than an hundred Potatoes each; the produce of which, for ten or twelve years after, will be prodigious [c].

Mr. Wimpey relates, that the firſt year he raiſed Potatoes from ſeed, he had ſome bulbs as large as a pullet's egg, but did not then remark any varieties. He preſerved the largeſt of theſe, and planted them in april following. In october they were carefully dug up, and were as large in general as thoſe produced from old bulbs: many from half a pound to a pound and upwards. Among them were five or ſix different varieties, totally different from the parent ſtocks: the colours ſmooth yellowiſh white, duſky brown, and reddiſh brown; the ſkin rough in ſome, ſmooth in others; ſome in diſtinct ſingle bulbs of a regular ſhape, others a congeries of bulbs from ſix to ten or twelve, connected by a kind of neck, compoſing a maſs, ſometimes nearly as big as a half-peck meaſure. One far exceeded all the reſt in beauty; many of theſe were as big as a gooſe's egg, having a fine clear ſmooth ſkin of a yellowiſh white colour, and finely pounced with ſmall crimſon ſpots; the complexion beautiful, and the ſubſtance admirably well taſted.

The bulbs from which the ſeeds of theſe varieties were obtained, were of very different ſorts: one, an oblong white Potato, many of which were gibbous at each end, connected by a part much ſmaller in the middle, a good family ſort. The other of a browniſh red colour, finely marbled on the inſide with a crimſon purple; a very fine juicy Potato, much in uſe for feeding hogs [d].

Dr. Anderſon alſo on the 23d of april ſowed on a bed of good garden mould, ſome ſeed of Potatoes gathered the preceding autumn, and preſerved among dry ſtraw all the winter. The young plants appeared in ten days, and advanced vigorouſly during the ſummer, eſpecially where they were not too thick. On the 3d of november they were taken up; ſome were nearly as big as a pigeon's egg, and the reſt gradually decreaſed to the ſize of peas. If the ſeeds had been properly ſeparated, they might have been ſown more equally; and if the plants had been tranſplanted, the roots would have been larger.

On the 20th of april the year following, theſe ſmall Potatoes were planted in a bed of good garden mould, in rows one foot aſunder, and four inches apart: decreaſing the diſtances as the bulbs diminiſhed in ſize. The largeſt yielded a good crop, in which many of the bulbs were as big as a hen's egg: but thoſe produced from the ſmaller bulbs did not in general exceed the ſize of a horſe bean, and many were no bigger than ſmall peas. None of the plants flowered.

Theſe Potatoes were planted in april 1778, in rows a foot diſtant, and the largeſt a foot aſunder in the rows. The largeſt again produced the moſt luxuriant and weighty crop. Very few flowered, and none of

the bulbs were of ſuch a ſize as thoſe produced from ſets of very large Potatoes; or afforded nearly the ſame produce as was obtained from them, planted on the ſame ſoil, at eighteen inches apart[e].

After this, Dr. Anderſon ſowed the ſeeds of a Potato which he received from Ireland, of a dark dirty purple colour, and a round irregular ſhape. It was planted by itſelf, at as great a diſtance as could be conveniently from any other ſort, and all the varieties in the neighbourhood were of the white ſort. The variety of the produce was very great, and ſcarcely two plants were preciſely the ſame. The colours were dark purple, bright pink, dark pink, bright white, dun, yellow, black, dark greeniſh, ſpotted, &c. The ſhapes very various. The time of ripening from auguſt to october. The ſize from a hen's egg to a pea. The ſtems, leaves, manner of growth, produce, &c. very different[f].

Application *or* Consumption.

By Man.

The reputation of the Potato as a wholeſome and nutritious food for man, has now been well eſtabliſhed by an extenſive experience of many years. The prejudices of ſome botaniſts on account of its natural place among the Solanums, ſome of which are poiſonous, has long ago ſubſided: indeed much attention was never paid to it. In Burgundy, it is ſaid, the culture and uſe of Potatoes in food were interdicted, as a miſchievous root. Among other effects, it was accuſed of occaſioning leproſy and dyſentery. There is not the ſmalleſt foundation for this: the roots however, expoſed to the ſun and weather, whilſt growing, acquire a green colour, a bitter taſte, and a narcotic quality[g]; the fruit alſo has proved noxious to ſome perſons, though not to others. A family having been accuſtomed to eat tarts made of this fruit, a ſtranger on putting the firſt bit into his mouth, clapped his hand to his throat, and declared he was choaked; he therefore eat no more, and the diſagreeable ſenſation went off as ſuddenly as it came. The family, notwithſtanding this, went on eating the tarts, without perceiving any thing in the leaſt degree offenſive: but ſoon after, one of the maid ſervants was affected in the ſame manner. Are not theſe two inſtances, aſks my friend, ſufficient to prove, that ſomewhat deleterious, though in a lower degree, reſides in this ſpecies, as well as in ſome of its brethren; and to confirm the propriety of Linneus's inſerting it in the genus Solanum[h]? At the ſame time, theſe inſtances are no proof of the inſalubrity of the root, properly cultivated; ſince it has now conſtituted the chief article of food to vaſt numbers of people, during a century.

It appears from Dr. Pearſon's experiments, that one hundred parts of Potato-root, deprived of its ſkin or bran, conſiſt of ſixty-eight to ſeventy-two parts of water, and thirty-two to twenty-eight parts of meal. The meal conſiſts of three ſubſtances: 1. Starch or fecula, ſeventeen to fifteen. 2. Leafy or fibrous matter, nine to eight. 3. Extract or ſoluble mucilage, ſix to five parts. This mixture is in many reſpects ſimilar to that of the grain of wheat and maize. The eſſential difference between them is, that the two latter contain a glue of the ſame nature as animal matter, in place of the leafy or fibrous vegetable matter of the Potato: but the principal ingredient in point of quantity in all is ſtarch, and they all contain a ſoluble mucilage. The mean quantity of animal glue in wheat appears to be about one twelfth of the meal. To this is imputed the ſuperior quality of wheat-meal for bread. It is ſuppoſed to give tenacity and firmneſs, at the ſame time that it promotes the fermentation in making the bread, as well as gives it a taſte.

Ninety-eight or ninety-nine parts out of a hundred of Potato-meal are capable of being aſſimilated into animal matter.

There does not ſeem to be juſt ground for the opinion that the meal of Wheat affords much more nouriſhment than that of Potatoes; for if it is ſuppoſed to be ſo on account of the animal matter which Wheat contains, the proportion of that is too ſmall to occaſion any great difference[i].

To obtain the meal from Potatoes, they are well waſhed, and grated down to a pulp, by a grater, or in a hand-mill. The pulp is then put into a hair ſieve, and repeatedly mixed with cold water, till the ſtrainings are clear, and the fibrous part perfectly diveſted of the meal. The former may be ſet aſide for the uſe of hogs or cows, and the ſtrained liquor ſuffered to ſettle, after which the brown-coloured water is poured off, and freſh water repeatedly mixed with the ſediment, and poured off after it ſettles, till the water comes off perfectly clear. The ſediment is then dried in the ſun or in an oven, as ſoon as may be, to prevent its ſouring. When quite dry, and put in a bag, in any dry place, it will keep many years. The quantity of meal will depend on the kind of Potatoes; but in general one pound of meal may be got from ſeven or eight pounds of the root[k].

By this proceſs the meal is deprived of the greateſt part, or all, of one of the ingredients, namely the ſoluble mucilage, which by itſelf is undoubtedly nutritive, and may probably be rendered more nutritive by mixture with the other conſtituent parts of the root.

To prepare meal therefore of the beſt quality for bread, the roots may be cut into thin ſlices, and dried quickly in the air of a kiln of the temperature from 110 to 130 degrees.

For want of the glue in Potato-meal, it cannot be made into bread alone; but with three or even two parts of Wheat-meal, or of the root itſelf, well boiled, peeled and maſhed, excellent bread may be made, with yeaſt, in the common method[l].

Wheat-meal having more animal glue than is neceſſary for making it into bread, and Potato-meal having none, a mixture may improve both. Sea biſcuits made with Potato-meal will certainly keep better, and be leſs liable to breed inſects[m]: biſcuits made with equal quantities of this and Wheat-meal, cannot be diſtinguiſhed from thoſe which are made wholly of the latter. Equal quantities of Oat and Potato meal unleavened or with a little yeaſt, make a cake or flat bread, more pleaſant to the taſte than when made only of Oat meal[n].

Potato-meal does not occupy near the ſpace of an equal weight of Wheat-meal. It does not abſorb moiſture. Having none of the animal glue, it is not apt to ſpoil, or breed weevils and other inſects. It appears to be indeſtructible in any common ſituations or circumſtances; and therefore is proper to carry into warm climates, and for uſe on board ſhips[o].

There is no doubt but that Potato-meal may be uſed, not only for preparing common ſtarch, but other ſubſtances of the ſame kind, as Sago, Tapioca, Vermicelli, Macaroni, and Salep; that it may be put to all the uſes to which ground rice is applied; and that it may ſerve, either alone, or with a due proportion of wheat-meal, in various compoſitions of cookery, ſuch as puddings, biſcuits, paſtry, &c.

It is however moſt ready, profitable, and perhaps ſalutary, to uſe the root cooked by merely boiling or baking. This is obviouſly the ſimpleſt and cheapeſt preparation. The meal is thus taken into the ſtomach, more intimately mixed or diffuſed through two and a half or three times its weight of water, than in the caſe of artificial mixtures of the meal with water. Hence the eaſineſs of digeſtion, and lightneſs of this root above other farinaceous ſubſtances equally nutritive. Hence alſo, this root alone, or with a little meat or oil affords ſufficient nouriſhment to moſt perſons without diſordering the ſtomach by its bulk: contrary to what is experienced from Beet, Turnep, Onion, and other roots, which contain a much greater proportion of water than that of the Potato[p].

Though the boiling of Potatoes is now conſtantly practiſed in moſt houſes in England, yet in many parts it is little underſtood. The Potatoes ſhould be ſorted, ſo as to be nearly of the ſame ſize; little more than water enough ſhould be put into the veſſel to keep them from burning, and if the roots be large, cold water ſhould be poured upon them once or twice; when they are ſufficiently done, pour off the water, and then evaporate the moiſture, by replacing the veſſel for a ſhort time over the fire. Some dreſs them in an iron pot, over a ſlow fire, without any water. Boiling by ſteam has been recommended as an improvement; but the water ſeems to carry off ſome matter, by detaining of which the flavour of the root is injured [q]. They are moſt agreeable and nouriſhing baked or roaſted.

The conſumption of this root in Ireland and Lancaſhire has long been very great, and is now become conſiderable in Scotland, and many parts of England. In the county of Fife 6000 acres are ſuppoſed to be annually planted with Potatoes; in Mid-Lothian from 1200 to 1500; in Roxburghſhire 1300 or 1400; in the Weſt Riding of Yorkſhire 1200; and about Frodſham in Cheſhire, 1300 acres [r].

In Ireland a barrel weighing 280 lb. or four Engliſh buſhels, will on an average laſt a family of ſix perſons ſix days; or a year's food amounts to ſixty barrels. Now the average produce of the whole kingdom being eighty-two barrels to an acre, plantation meaſure, one acre rather more than ſupports eight perſons the year through, which is five perſons to an Engliſh acre. To be fed on Wheat, thoſe eight perſons would require eight quarters, or two Iriſh acres, which in the preſent mode of culture, imply two more for fallow, or four in all [s].

Mr. Bartley, of Briſtol, calculates, that a ſack of Potatoes, weighing 224 lb, and containing one fourth part of farinaceous matter, is at leaſt equal in value, as an article of food in the family of a poor cottager, to a buſhel of the beſt Wheat: and that by a judicious attention to ſoil, ſituation, ſeaſon, &c. 120 ſacks of Potatoes may be more certainly raiſed upon an acre than twenty-five buſhels of Wheat. But that on ſtiff clays and wet heavy ſoils, not only light crops are to be expected, but a diminution of the farinaceous matter, and a degeneracy of the root [t].

According to Mr. Harris, a labourer with three or four children will uſe from twenty-five to thirty-five buſhels: ſuppoſe the average produce 180 buſhels to the acre, (of 90 lb. to the buſhel:) a ſixth part of an acre will ſuffice for ſuch a family [u].

Again, if an acre produce ten tons or 300 buſhels, there will be about twelve pounds a day, for the conſumption of each perſon in a family of five, and therefore the ſixth part of an acre will be ſufficient to afford them two pounds a day, the year through. But if they live on Potatoes only 250 days in the year, an acre will afford each perſon 18 lb. daily, and therefore a ninth part of an acre will ſuffice for ſuch a family.

If every cottage therefore had an acre or even half an acre aſſigned to it for a garden, there would be ample room to furniſh the family with this nouriſhing root, together with a change of ground for other vegetables. But this would be to little purpoſe without manure; and that can hardly be procured in ſufficient quantity, without a cow, or at leaſt a pig. Where this cannot be done, gentlemen and farmers may give or let pieces of land in odd corners of incloſed fields, headlands, &c. to their labourers, and theſe will bear a tolerable crop for two or three years, with little or no manure. Or farmers may find land, ſets and manure, and divide the produce with his labourer, who is to perform all the work. Or a certain quantity of a fallow intended for Wheat, and well manured, may be ſet apart every year for this purpoſe, under certain conditions, advantageous to both parties.

In Ireland a family of five perſons will eat and waſte forty-two ſtones of Potatoes in a week; but then the cows, pigs, poultry, &c. all partake with them. This root is well known to be the general food of the lower people, for a great part of the year.

In Scotland, the uſe of Potatoes has very much increaſed. In the central highlands they are become the principal food of the common people; and before their introduction famines were frequent there. It would be difficult to ſay how much the introduction of Potatoes into the Hebrides has bettered the condition of the poorer inhabitants. In Eaſt Lothian they conſtitute nearly one-third of the food of the common people, from the firſt of auguſt to the end of may. In Perth they are ſaid to have done more to prevent emigration than any device whatever. In Banff, had they not been in general uſe in the year 1783, it is probable that many perſons would have periſhed for want of food [x].

In many parts of Wales, Potatoes and Barley bread form the chief ſuſtenance of the poor.

In England; it is no uncommon thing in Somerſetſhire, for families to live three quarters of a year on Potatoes; and the want of them would bring the whole family to the pariſh. In Lancaſhire and Cheſhire the uſe has been long general and extenſive [y]. It is very conſiderable in many other parts; and in the metropolis the conſumption is very great.

Yeaſt or Barm may thus be made from Potatoes. Boil ſome of the mealy ſort, (one pound for every quart of yeaſt to be made,) till they are quite ſoft: ſkin and maſh them very ſmooth: mix as much of the water in which they were boiled as will reduce them to the conſiſtency of common yeaſt, but not thicker. Add to every pound of Potatoes two ounces of coarſe ſugar or treacle; and when lukewarm, ſtir in, for every pound of Potatoes, two table ſpoonfuls of good new beer yeaſt. Keep it ſtirring and warm for twenty-four hours, or till it has done fermenting, when it will be fit for uſe; but if older, the better. It will keep in bottles three months [z].

An ardent Spirit may be obtained from Potatoes. Many years ago it was propoſed in Sweden to uſe them for this purpoſe to ſave corn; and it was found that an acre of land ſet with this root would yield a greater quantity of ſpirit than if it were ſown with Barley [a]. Hence the practice was taken up in ſome parts of Scotland. Different accounts are given of its quality there; owing probably to more or leſs ſkill and care in the proceſs. Dr. Anderſon obtained from ſeventy-two pounds of Potatoes an Engliſh gallon of pure ſpirit conſiderably above proof, and about one quart more below proof. He celebrates it as the fineſt and moſt agreeable vinous ſpirit he ever taſted: ſomewhat like very fine brandy, but more mild, with a peculiar coolneſs upon the palate, and a flavour as if it had been impregnated with violets and raſpberries. The Potatoes were boiled to a pulp, bruiſed and paſſed through a ſieve with freſh water, to ſeparate the ſkins. The pulp was then gradually mixed with about twenty gallons of cold water. When this mixture was of a temperature fit for putting yeaſt to wort, yeaſt was put to it. In ten or twelve hours a fermentation began, and continued during ten or twelve hours; by ſtirring it briſkly this was renewed, and continued for a fortnight, at the end of which time it could not be renewed by agitation or otherwiſe, and was found upon trial to have acquired a kind of acid ſlightly vinous taſte fit for diſtillation. It was then diſtilled with due caution; care being taken to ſtir it till it began to boil, before the ſtill-head was applied; and the fire was made ſo ſtrong as to keep it boiling briſkly, till the whole came over, in order to prevent the thick matter from ſubſiding, and burning to the bottom, which would have given it a flavour like the fumes of burning tobacco. For want of ſkill or caution, ſpirit ſaid to be drawn from Potatoees has been found to be intolerably nauſeous: but Dr. Anderſon ſucceeded equally well a ſecond time. Another perſon however under his direction could not ſucceed in producing that

peculiar raſpberry-flavour, though in other reſpects the reſult was the ſame [b].

If the produce of an acre be ten tons or 300 buſhels, it is obvious that full 300 gallons of ſpirit may be expected from it.

By Horſes.

Sir William Fordyce ſeems to have been the firſt perſon publicly known in England to apply this root to feeding horſes. He gave them boiled in the uſual manner, and each horſe had a quarter of a peck daily. The ſort was the Cluſter or Surinam Potato. The horſes did their work well on this allowance, with a trifling quantity of Oats now and then, during two months. If they were baked or roaſted on kilns, as they are in Northumberland, and mixed with ſome ground Oats, it would be a great ſaving in corn, and more hearty food. Mr. Kirby, of Ipſwich, gave them raw, but waſhed, to ſaddle horſes, each a peck a day, without any Oats. They did their work very well, and were in good order. At firſt they ſcoured, but it ſoon went off, and only kept their bodies gently open. Reckoning half a peck a day to be equal feeding, and the price of Oats ſixteen ſhillings a quarter, the value of the Potatoes will be one ſhilling a buſhel. Mr. Bywell gave half a peck a day with hay, but no Oats, to draught horſes, and never had them in ſo good condition: he recommends them as a remedy for ſwelled legs, and uſed them raw [c]. Mr. Young gave rather more than two pecks a day to each horſe; and found that they did not eat ſo much when given raw.

A gentleman in Lancaſhire fed forty horſes with Potatoes boiled in a baſket, half a buſhel to a buſhel of chaff, without any Oats. One woman waſhes and boils twenty-five buſhels in a day. The whole prime coſt of the Potatoes ready for the manger ſeven pence the buſhel [d].

Mr. Stewart fed two horſes a whole winter, that regularly ploughed an acre a day, on Potatoes and cut ſtraw, without hay or corn: the Potatoes were waſhed and boiled at the expenſe of three halfpence the buſhel: the two horſes ate nine buſhels a week, were in high order, and ſtood their work well [e].

Of all applications, in Mr. Young's opinion, none anſwer any thing like that of giving them, late in april and may to cart-horſes and working oxen: when hay is ſcarce and dear, it may thus be ſaved to very great advantage [f].

In confirmation of this, Mr. Culley remarks, that they have for ſeveral years practiſed giving their working horſes Potatoes in the ſpring, with the greateſt ſucceſs. They give corn at the ſame time, becauſe they work their horſes remarkably hard at that ſeaſon. They think that Potatoes with their corn and ſtraw, not only keeps them heartier, but prevents greaſe, foulneſs, &c. by keeping their bodies open [g].

Mr. Dann, of Gillingham in Kent, gave eighteen buſhels of Potatoes, with chaff and cut ſtraw, two buſhels of Beans, and two buſhels of Oats weekly to three teams of cart-horſes. The Potatoes ſaved four buſhels of Oats weekly; which aſcertains the value to be twelve ſhillings, or eight pence the buſhel. The teams were in as good, or perhaps better order, than when fed without Potatoes [h].

Mr. May, near Ipſwich in Suffolk, keeps nineteen horſes and four cows on a farm of ſix hundred acres, without a ſingle acre of meadow or artificial graſſes. His entire dependance, in winter and ſpring, is on Potatoes, chaff and ſtraw. He gives one buſhel a day, cut very ſmall; for if uncut or but groſsly, they will not eat a ſufficient quantity of dry meat with them. The ſort he uſes is the Ox-noble [i].

Mr. Crooke, of Tytherton in North Wiltſhire, fed nine horſes with ſteamed Potatoes at three halfpence the buſhel, with as much cut ſtraw as they would eat, but no oats, nor hay [k].

At Aveley in Eſſex 300 lb. ſufficient for a working horſe ſix days, which is 9000 lb. for half a year, being three-fifths of an acre's produce. Waſhing and ſteaming coſt two pence for each 100 lb. To every 300 lb. half a pint of ſalt, and a ſmall quantity of ſulphur were added. On a compariſon of wintering a team of five horſes thus, and with hay and oats, it was in favour of the former 12l. 17s. [l]

Mr. Young, in various experiments, aſcertained the value of the Cluſter ſort, for feeding horſes to be nine pence the buſhel. Others have found them to be worth a ſhilling, and Mr. Billingſley eſtimates them at eight pence for this purpoſe [m].

In many parts of Scotland they are given to horſes raw, but well waſhed, and are found to be excellent. In Annandale 10 lb. are ſuppoſed to be a moderate feed. In Eaſt Lothian horſes prefer Surinam Potatoes to corn; when accuſtomed to them; they are eſteemed excellent for foals and young horſes, keeping them open in body, and ſmooth in coat: 9 lb. are a ſufficient feed for a pair of horſes, with half the uſual allowance of oats. In Fife they give a peck a day to each horſe, and regard them as excellent for horſes. In Kintyre (Argyleſhire) their working horſes have generally one feed of Potatoes: from 15 to 18 lb. make a good and cheap meal for a horſe [n].

In Ireland, Mr. Longfield, of Caſtle Mary, cultivates the Cluſter Potato, which they call Bulls. Horſes are very fond of them; they do very well on them raw, but better when boiled [o].

Here is much in favour of Potatoes as food for horſes, and yet it is aſſerted, that in ſome parts of Scotland Surinam Potatoes otherwiſe called Yams have been diſcontinued, being found to produce gripes and colic. The Rev. Mr. Cloſe ſays, they have not anſwered with him ſo well for horſes and colts as he expected [p]. I have been told that a gentleman ruined a fine team of horſes, by feeding them on raw Potatoes.

By Cattle.

Experiments on giving Potatoes to milking cows turn out much in favour of this root. Dr. Wilkinſon, of Enfield Chace, gave them to a dairy of ten cows. At firſt not above half the cows took kindly to them; by degrees however they all became fond of this food, and at laſt, towards ſpring, as the fodder became dry, would ſcarcely taſte any hay, and were almoſt entirely kept on Potatoes, each cow conſuming about a buſhel every day. The milk being applied chiefly to ſuckling, the increaſe was not aſcertained, it was however evidently great. The butter was well-flavoured, and better than it had been the preceding winter. The cows were kept rather looſe in their bodies, but preſerved their health, and looked ſleek and thriving through the winter. But for the laſt fortnight, when they all began to reject hay, and lived almoſt entirely on Potatoes, the milk became too thin and watery to bring the calves on properly, and the butter became white and taſteleſs, without any firmneſs or adheſion [q].

Mr. Forby finds that Potatoes give a bad taſte to milk [r]. Mr. Cloſe fed his three cows, after Cabbages, with half a buſhel of Potatoes night and morning, and a ſmall quantity of hay, from the 10th of march to the 10th of may, without any diminution of their milk, but rather an increaſe of cream; the butter as ſweet as from the beſt graſs. All cattle may thus be fed to great advantage, at leaſt during the month of april, and the firſt fortnight in may, which practice would enable the farmer to clear his turnep or cabbage land, and to ſow his ſpring corn at an early and proper ſeaſon [s]. Charles Mordaunt, Eſq. gives one peck boiled night and morning to each cow [t]. Mr. Seaton, of Suſſex, gave at leaſt half a buſhel each to three milch cows from the firſt of november to the firſt of april, and fed three heifers in calf from the 13th of february to the 10th of april [u].

T. B. Bayley, Eſq. of Hope ſays, that his cattle

eat the Howard or Bedfordſhire Potato boiled, with as much eagerneſs as the beſt ſorts, and came on as well with them; that for the milch cows he mixed malt-duſt with them, and found them much more profitable than either Turneps or Cabbages. Once, when his Potatoes grew low, he deſiſted from giving them to the milking cows; immediately, though fed with the beſt hay, they fell off much in their milk; he therefore began again, and in a week they yielded more butter by one third. Their value is ſuperior in this to Turneps or Cabbages, and there is no riſk of their giving a diſagreeable taſte either to butter or milk [x].

A large cow, tied up a month after calving, ate 2 cwt. and 18lb. of hay in one week, and the enſuing week four Wincheſter buſhels of Potatoes being given to her, the conſumption of hay was reduced to 3 qrs. and 20lb. It appears therefore that a ſack of Potatoes is equal to 1 cwt. of hay. The quantity of milk was increaſed by the Potatoes, but it was thinner in quality [y].

In the Lancaſhire Report, Mr. G. Green obſerves, that after many experiments he invariably found that the watery Potato, of which there are many varieties, has fallen far ſhort of the purpoſe intended: that he has ſeveral times, both through neceſſity and for the ſake of experiment, given the Ox-noble to milch cows, after the more farinaceous ſorts, as for inſtance the Pink-eye, when the decreaſe of both milk and butter has been evident in a very ſhort ſpace, and the beaſts themſelves ſeemed much diſſatisfied with the change.

In the Report for the county of Fife, Potatoes are ſaid to be exceedingly proper for milk cows, and by ſome are reckoned preferable to Turneps; as they produce an equal quantity of milk, and give no bad taſte either to milk or butter. But as cows are in danger of being worried or ſuffocated with Potatoes, it is adviſeable to cut or maſh them.

Sir Mordaunt Martin obſerves, that when he fed his cows with Potatoes, they were all ſo tender-footed, as to be hardly able to walk from the yard to an adjoining cloſe: this he attributes to their treading in the dung formed by the Potatoes; for they ſoon recovered when they ceaſed to eat them [z].

In Cheſhire they are found to be of too laxative a nature, without the addition of ſome other food.

In Dumbarton cows are fed with meſſes of boiled food, in which Potatoes are a principal ingredient, not boiled but bruiſed in a ſtone mortar.

In Mid Lothian the Surinam is chiefly given to milch cows; increaſing the produce without affecting the taſte of the milk. In Weſt Lothian theſe have killed many cattle by hoving. Mr. Hill, of Hertfordſhire, finds that milch cows yield abundance of milk with Potatoes, but not cream in proportion [a].

Some perſons have uſed the ſtalks of Potatoes, as a food for horſes and cattle: but if they are cut whilſt the roots are growing, the crop of roots will be leſſened; and if the cutting be delayed till the growth of the roots is completed, they will not be either ſucculent or nouriſhing. At beſt I believe they are but indifferent food [b].

Potatoes have been uſed by ſome for fatting cattle, in their opinion, with great ſucceſs: but others have diſputed the economy of it. Mr. Bywell of Yorkſhire fed oxen of ſeventy or eighty ſtone, with a buſhel a day, and ſome hay; and found them ſuperior to Turneps. Mr. Campbell found that large oxen may be as completely fattened on potatoes and hay, as on any other food. Mr. Arthur Young finiſhed fattening oxen with Potatoes, with the addition of ſome beanmeal from april 21ſt to may 27th, and they did perfectly well. Mr. Abdy of Eſſex fattened Welch runts on Potatoes, and a Scotch cow. Several perſons in Suſſex have uſed them for fattening oxen, and found them to anſwer, paying from 4d. to 9d. a buſhel [c]. Mr. Hunter of Hertfordſhire fed 103 oxen on Potatoes, and found they did well with hay, but not without [d].

Mr. Dann of Kent, after fattening many beaſts with this root, dropped the practice in 1794, finding that it did not anſwer. Mr. Arthur Young, in fattening eight bullocks, tried 212 buſhels of Cluſter Potatoes, with bean-meal and chaff, and found that they did not pay three halfpence a buſhel; that ſeventy buſhels more were given to loſs; and that in finiſhing twelve beaſts the year after, the reſult was loſs. Another time, he gave to ſix fattening beaſts, during three weeks, Potatoes, Beans, and Hay; the 126 buſhels of Potatoes paid only one penny the buſhel. Mr. Mure of Suffolk, fattening beaſts on a very large ſcale, with Potatoes, Beans, Chaff, and Hay; found that the Potatoes to the amount of many thouſand buſhels paid nothing. In one experiment they paid 6d. and in another 2d. halfpenny [e].

In Ireland, Mr. Jones had twelve ſtore bullocks on Potatoes; they liked them much, and eat three barrels a day. They weighed 5 cwt. each, and had they been kept long enough on the Potatoes would have been fattened [f]. Mr. Rowley has fattened worked oxen of five years old, in eight weeks on Potatoes parboiled, with hay [g]. Mr. O'Hara of Nymphsfield fatted many bullocks with them, and found that they did exceedingly well [h].

Mr. Cloſe of Suffolk allows his fattening cattle all the Potatoes they will eat: a beaſt of about 35 ſtone, will require a buſhel every day, but will fatten one third ſooner than on Turneps. He waſhes them clean, and does not give them until they are dry. He boils them only for bacon hogs and poultry; and prefers the Champion [i].

Mr. Turner, of the ſame county, finds that bullocks do exceedingly well on them: that four, of 35 ſtone each, will eat 16 ſacks a week, and 7 lb. of hay each every day: and that when they take to them kindly, nothing will bring on beaſts faſter than Potatoes [k]. A gentleman from Lancaſhire fats many oxen on them boiled, and finds that they, and all other animals, do much better on them boiled than raw. On which Mr. Young remarks, that baking is ſaid to be ſtill better [l]: but he does not admit, that Potatoes applied in any way to this purpoſe will anſwer.

Mr. James Bucknell, of Knowſtone near Tiverton, Devon, found that this practice far exceeded what he expected. Cattle, when a little uſed to Potatoes, grow exceeding fond of them, but it is neceſſary to give them ſometimes oat-ſtraw and hay: the former is particularly uſeful, to prevent that laxative ſtate of body, which the cattle would otherwiſe be ſubject to, from the rich and nouriſhing quality of the Potatoes, if confined wholly to that ſort of food. Cattle thus fed were generally diſpoſed of to the butcher, and the beef was exceeding well taſted. The number he thus fed yearly was about fifty. He gave the Potatoes raw and unwaſhed [m].

John Hunter, Eſq. of Gubbins in Hertfordſhire, fattened 103 oxen principally with Potatoes, and 70 capital cattle the year after. They are wonderfully nutritive, but will not fatten an ox in any reaſonable time without hay [n].

William Barbor, Eſq. of Fremington near Barnſtable, Devon, fed 56 bullocks on twenty acres of Potatoes. The cattle were bought in very lean, and ſcoured for three weeks; after this ſtopped, they throve very well: this food had no ill effect on thoſe that were in a better ſtate. The beaſts are ſubject to ſwelling and being choaked: but the firſt is eaſily got rid of by driving them about the yard, and the ſecond may be prevented by thruſting down the Potato with a ſmooth ſtick, or a large ſtiff rope ſoft at one end. The 56 bullocks were bought in for 380l. 18s. and were ſold for 580l. 18s. Each bullock eat three pecks a day, which at the rate they then ſold for was 2s. 6d. a week. They were put to feeding on the 10th of december, and moſt of them were fit for the butcher by the 1ſt of march; but the number being too great for the conſumption of the

country,

Digitized by Google

country, they were ſold as purchaſers offered, and were all gone by the 4th of may, except four, which were not ſold till the end of the month. They were all ſold to the butcher except three, which were diſpoſed of to a jobber, and moſt of them were killed immediately from the ſtalls. For the firſt week he gave them hay, but finding that too expenſive, he changed it for ſtraw, which he found to anſwer full as well [o].

By Sheep.

Sheep have not been ſo generally fed with Potatoes as bullocks. Mr. Fuller of Suſſex however has fattened many ſheep on them with great ſucceſs, and faſter than on corn or even oil-cakes; each ſheep eat a gallon every day, and ſome hay morning and evening. The Potatoes were ſliced, and put into troughs under a ſhed. The ſheep were of the South-Down breed; were taken into the yard about the middle of november, and were ready for the market at the end of february, or the firſt week in march [p].

General Murray, of the ſame county, fattened ſheep with them; 196 wethers eat very near 14 buſhels of Potatoes, and 1 cwt. of hay each day [q].

Monſ. Cretté de Palleul fattened ſixteen ſheep: four on Potatoes, four on Turneps, four on Beets, four on Corn. The four on Potatoes gained in four months 70 lb.—on Turneps, 67 lb. ½—on Beets, 71 lb.—and on Corn, 92 lb. ½. They had ſome hay; and were all weighed alive [r].

George Ward, Eſq. of Bradfield houſe in Berkſhire, found that an acre of middling Turneps, and 100 buſhels of Potatoes, kept forty lambs the ſame time, namely twenty days. The ſcouring at the beginning was ſtopped by a little hay. When the Potatoes were finiſhed the lambs fell off [s].

Mr. Dann, of Gillingham in Kent, made a reſerve of Potatoes for ewes and lambs in the ſpring, that Turneps might not remain to exhauſt the land, to the injury of ſucceeding crops. From the 2d to the 14th of april incluſive 156 ewes, and 155 lambs, were kept in a meadow of five acres and three quarters, on Potatoes and Clover hay. They eat each 616 lb. of the former, and 279 lb. of the latter. This ſaved the Clover, of which there was then a very ſhort bite. Mr. Dann is of opinion, that if feeding with Potatoes were continued, till Lucerne and Clover could be mowed for the ſheep, it would be a great ſaving, as the produce will be conſiderably more when mown, than if they were fed [t].

William Barbor, Eſq. during winter, eſpecially in bad weather, to about ſix ſcore ewes gave ſometimes a bag of Potatoes, containing twelve pecks, Wincheſter meaſure, to every ſcore, in a day. They were carried out, and thrown abroad on the paſture. After having been uſed to them two or three days, they eat them with great eagerneſs [u].

Mr. Armſtrong, of King's county in Ireland, had eighty ſheep in the ſnow, which got to his Potatoes, and eat of them freely, upon which he picked forty of them, and put them to that food regularly: they fattened very quick, much ſooner than forty others at hay, and yielded him a great price [x].

The moſt unſucceſsful experiment I have met with on feeding ſheep with Potatoes, is Mr. Arthur Young's. November the 21ſt he found ſixteen of his wethers to weigh alive 1432 lb. He incloſed them on dry graſs, in a pen, which was moved occaſionally. January the 14th he weighed them again, and their weight was then only 1264 lb.; they had loſt therefore 168 lb. after having eaten ſixty buſhels of Potatoes. So he finiſhed an experiment ſo manifeſtly miſchievous, by putting the ſheep to Turneps. This was the Cluſter Potato [y]. Sheep will not always take to Potatoes at firſt, without ſlicing and mixing them with other food.

By Swine.

Potatoes have been applied with ſucceſs to feeding ſwine, and to fattening them, with the aſſiſtance of meal, peas, &c.

In Cumberland, thirty buſhels of Potatoes, and ten of Corn made into meal, are ſuppoſed to feed a ſow of eighteen or twenty ſtone weight, and leave a profit of 1l. 15s. The Potatoes are boiled, and the meal is mixed with them. Thus applied they are worth 4d. a buſhel.

Mr. Billingſley of Somerſetſhire found their value thus applied, did not exceed 10d. the buſhel of 80 lb. and that they may be grown for 6d.

In Staffordſhire, refuſe Potatoes are very generally applied to fatting hogs, which they will bring on faſt when boiled, and mixed with a little ground Barley; the tail or damaged Barley will anſwer the purpoſe.

The Reporter for the county of Fife, ſays that nothing is preferable to Potatoes for rearing or fattening hogs; and that he has ſeen ſome fed to a large ſize, and of excellent quality, who had nothing but Potatoes raw or boiled, except a little peas or oat-meal mixed with them a few days before killing [a].

Mr. Turner kept ſixty hogs a conſiderable time on the Red Cluſter Potato: but thinks that they grow tired of them, and do not come on faſt enough in fleſh; and that it is therefore more profitable to give them Beans occaſionally, or to let them have the run of a barn door. On this Mr. Young remarks, that from a conſiderable experience in keeping a large lean ſtock with the Red Cluſter, he has found that they may be depended on without other food; but that fattening even for roaſting pork is a different queſtion.

Sir William Fordyce fattened hogs with the Cluſter Potato, except the laſt ten days, when he gave them Peas; and did not find that the fat was loſt in boiling.

Mr. Cloſe (1784) for ſeveral years kept his hogs on his refuſe Potatoes; and finds pork fed with them remarkably ſweet, moiſt and delicate. Bacon hogs he keeps about a fortnight upon ground Peas mixed with the Potatoes boiled. If they be forwarded with Potatoes before they are confined, two buſhels of Peameal, and four buſhels of boiled Potatoes, well incorporated, will fat a hog of twelve ſtone, fit for hams or bacon [b].

Mr. Le Blanc applied 166 buſhels of Cluſter Potatoes to feeding fourteen hogs taken out of the ſtubbles above half fat: they had a buſhel raw, three times a day; no corn, but the ſhack of a farm-yard, in which three flails were going, with fifteen little pigs, which in return took a ſmall ſhare of their Potatoes. After having been thus fed above three weeks, and thriving very faſt, they were ſold to the butcher [b]. The ſame gentleman had afterwards thirteen ſows with their litters at once on Potatoes, and ſhould not have thought of keeping ſuch a ſtock, had it not been for this proviſion [c].

Mr. Pitt of Pendeford fattened large ſwine with Potatoes boiled, and thickened with bran and barley flour. On taking the Potatoes hot from the furnace, in maſhing they were mixed with the bran and barley-meal; 12 lb. ½ of the latter to one buſhel of Potatoes. Afterwards they had Peas [d].

Mr. Boys of Kent, found that ninety-ſix ſacks of Potatoes, given to fatten hogs, were 4l. 3s. 1d. worſe than nothing. Upon which Mr. Young remarks, that this experiment tends to confirm the opinion that Potatoes alone will not fat hogs; but does not by any means prove, that they may not be profitably uſed with corn, either raw or boiled [e].

Mr. Adams, of Cherington near Newport in Shropſhire, fatted eight pigs, by placing two troughs in the ſty, one filled with raw Potatoes, the other with Peas. They had no water, ſo that when the pigs were thirſty, they ate the Potatoes. They were fatted from ſixteen to twenty ſcore; and ate no more than thirty buſhels of Peas, and 200 buſhels of Potatoes [f].

Mr. Fawkener, of Petworth in Suſſex, having found that his hogs fell off their fleſh and did badly on raw Potatoes, was induced to ſteam them, which is ſuppoſed to be better than boiling; the water in which

Digitized by Google

Potatoes are boiled being deleterious to hogs[g]. But does not boiling carry off this deleterious ſubſtance into the water better than ſteaming?

Mr. Billingſley found that the water in which Potatoes were boiled was injurious to hogs. He alſo plainly perceived, that they were better liked when ſlightly boiled, than when boiled to a pulp[h]. He gives a decided preference to large hogs; the ſmall growing pigs eating nearly as much food, without improving proportionably in ſize or fat. He found that many hogs at firſt ate the Potatoes with reluctance, particularly when raw, and that the quantity of food conſumed increaſed every week, till the animal became three parts fat; after which they ate little, and almoſt all they did eat turned to fat. He experienced a great amendment in the quality of the waſh, when a quantity of meal was mixed up a week or two before it was uſed, to ferment. Salt given with the Potatoes tempts the hogs to eat them very greedily. A little malted Barley, or Oats, mixed in their waſh would do good. It appears that no ſwine pay better for Potatoes than ſpayed ſows; for they get fat quicker and on leſs food than others. Grinding Potatoes in a mill inſtead of boiling did not anſwer; but they might perhaps if they had been mixed with meal, and fermented in a reſervoir. Upon theſe experiments of Mr. Billingſley's, made upon a very great ſcale, with an ample capital, and the utmoſt attention and care, Mr. Young remarks, that the profit is nothing, the loſs certain, and would have appeared ſtill greater, if intereſt on capital had been reckoned[i].

Sir Thomas Beevor gave them boiled to fattening ſwine, but did not find them anſwer alone; but mixed with an equal quantity of Barley or Buck meal, he has had them equally fat, and in as ſhort a time, as thoſe which were fed with either of the meals alone[k].

Mr. Charles Chaloner recommends baked Potatoes as an excellent food for hogs. The pork was equal to that from Barley and Beans. The Potatoes were done on a kiln, ſimilar to what is uſed by oat-meal ſhellers for drying their Oats. The difference in expenſe between boiling and baking is prodigious, both in labour and fuel. The action of the fire, by diſſipating the crude juices, reduces the Potatoes to a ſtate highly wholeſome and nutritious. Boiling does this in part, but not ſo effectually as baking or roaſting[l].

Mr. Robinſon, of Steeple Langford, Wilts, fed eight large hogs from the 27th of january to the 21ſt of april, when the laſt was killed, on boiled Potatoes only. The Potatoes, after being boiled, were drained in hampers, put into large buts, and rammed down hard with a beetle: from theſe tubs they were dug with a ſpade, and carried directly to the pig-ſty. The pigs always ate them with appetite, and throve upon them well, though not ſo rapidly as upon Pea and Barley meal. The bacon was as ſweet, firm, and as little waſteful as when hardened by corn[m].

Mr. Young aſcertained the value of the Cluſter Potato in feeding ſwine to be on an average 8d. farthing a buſhel. He boiled them, being firſt well waſhed, in a copper, maſhed them in a tub, when they were turned into a ciſtern, and incorporated with Barley meal, nine buſhels to ſeventy-five buſhels of Potatoes. The common ſtock do very well on them raw, and they may be thrown to them from the heap every day with little trouble. A large boar, three ſows, and eight ſtores had no other food from november to the end of june: two buſhels a day kept theſe hogs in high order. An acre therefore (or 360 buſhels) would maintain twelve middling hogs ſix months or 180 days. But Mr. Young is confident that two buſhels a day will maintain ſixteen hogs[n].

Mr. Kendal of Derbyſhire mixes two buſhels of Rye-meal with twenty of boiled Potatoes; with which he fattens brawns better than on corn alone. Mr. Wharton of Doncaſter mixes half a peck of Barley-meal with ſix buſhels of Potatoes boiled, with which he fattens porkers, and half fattens bacon hogs. Mr. Arbuthnot fattens porkers with Potatoes mixed with a little Barley-meal. Mr. Poole of Suſſex, boils one third Barley-meal, and two thirds Potatoes which beat Peas and Barley alone[o].

In Ireland, Mr. Clements at Killadown finds that hogs fat exceedingly well with boiled Potatoes, without any meal, both for porkers and bacon; giving them Oats for three weeks at laſt.

About Luttrelſtown they give their pigs the ſmall Potatoes boiled, and they fatten them to fine bacon; but they give ſome butter-milk, and a week or two before they are killed, ſome offal corn.

At Slaine they fat hogs with them boiled; at laſt mixing ſome Bran or Oats. A hog of two cwt. will fatten in two months on ſix barrels of Potatoes, and one barrel of Oats. Potato-fed pork reputed much firmer than that fed on Pollard. About Headfort all the hogs are fattened on Potatoes half boiled.

Mr. Cooper of Mercra has found that Potatoes raw will fatten hogs very well, but the fat will be flabby and greaſy; but if they be parboiled and well ſprinkled with ſalt, the fleſh will be firm and perfectly good[p].

By Dogs.

Potatoes boiled, maſhed, and mixed with meal, are an excellent food for dogs. Eight ounces of Potatoes with one ounce of meal are equal to four ounces of meal alone.

Suppoſe a dog to eat 5 lb. 4 oz. of meal in a week; with 10 lb. 8 oz. of Potatoes he will require only 1 lb. 5 oz. of meal: which will make a ſaving of almoſt one half.

By Poultry.

Conſiderable profit may be made by feeding geeſe, turkeys, and fowls of every ſort, with Potatoes boiled and mixed with meal as above. They will feed fatter, and in nearly half the time that they will with corn, or even meal by itſelf[q].

In Ireland they are very commonly applied to feeding poultry. They boil them to a maſh, and mix them with butter-milk. Much poultry is thus reared and fed in all the cabbins, in many parts of the country[r].

Sir William Fordyce fed his fowls entirely on Potatoes and Pollard, and found that they throve exceedingly on this food, and that it was a great ſaving in grain[s].

Upon the whole, Potatoes are a very valuable article for rearing and feeding ſtock of all kinds, when judiciouſly managed: and may always be thus turned to account, when raiſed in quantities too great to fetch a price at market, or in places too diſtant to pay the expenſe of carriage. The profits on feeding ſtock are ſeldom conſiderable, but when we reflect on their great importance in the ſpring, when Hay is dear, and Turneps fail, on the good ſtate in which Potatoes well managed leave the land for ſucceeding crops, and the great quantity of the beſt manure which is raiſed from them, we cannot but acknowledge that they are, upon the whole, beneficial to the farmer.

Effect upon Land.

It is much diſputed whether Potatoes exhauſt the ſoil or not. There can be no doubt that they do, under improper management; and that although ſome perſons have raiſed them four, and others even thirty-two years ſucceſſively on the ſame land, yet no prudent cultivator will continue them longer than two years together, except in highly manured ground, or in gardens and ſmall patches, where particular attention is beſtowed on them. On a large ſcale, they ſhould always come in regularly with other crops.

Many, ſays Mr. Billingſley, object to the cultivation of this root on a large ſcale, conſidering it in the light of a great exhauſter. If the produce of any crop, ſo productive as this is, be ſold from the farm without ſufficient return of manure, ſuch muſt be the effect; but if Potatoes are conſumed on the premiſes, the manure from the conſumption of one acre, will be ſufficient for two or three: and as the Potato crop ought always to be highly manured, no deficiency

Digitized by Google

need be feared in the ſubſequent crops of grain, graſſes, &c. eſpecially if Wheat be baniſhed, and Barley or Oats ſubſtituted in its place[t].

Mr. Tuke, the agricultural reporter for the North Riding of Yorkſhire, has always found that the crop of corn ſucceeding Potatoes, and the ſeeds after the corn, have been equal to thoſe which ſucceeded a crop of Turneps. A well managed crop of Potatoes leaves the ſoil in a mellower and more fertile ſtate than any ſummer fallow, from the frequent ſtirrings for the deſtruction of weeds: the thick ſhade of the plants, which keeps a perpetual moiſture in the ſoil, and the decay of a large quantity of leaves and ſtalks, before and after the crop is taken up, all tend to enrich the ſoil. And do not all ſucculent plants derive a great proportion of their nouriſhment from the atmoſphere?

Mr. Young remarks, that even if the Potato ſhould be found to exhauſt conſiderably, as he ſuſpects it does, yet the friends of this culture ſhould not be alarmed at it; for though it is a deduction from its value, ſtill that value in its product is ſo very conſiderable, as to leave it one of the moſt beneficial plants that the farmer can put into his ground[u].

Potatoes are not regarded as an exhauſting crop in Eſſex, where they cultivate them on a very great ſcale. Mr. Turner of Stoke near Ipſwich aſſerts from the experience of ſeveral years, that they are by no means exhauſting, but on the contrary an ameliorating crop; and that his Barley after them had not a weed, and produced five quarters an acre. Mr. Bucke of Worlington in Suffolk judges, from his ſecond crop exceeding the firſt, with only a ſmall quantity of dung, that this crop is not very exhauſting. Mr. Lodge of Great Blakenham in Suffolk never found the idea that Potatoes are an exhauſting crop verified; is certain that no crop leaves the land ſo clean; and uſually ſows Barley after them with good ſucceſs[x].

In Durham they ſow Wheat after Potatoes, and have good clean crops. In Suſſex the Wheat following this root is reputed equal to that of a Clover lay, or clean fallow[y].

Mr. Groſett of Cornwall is ſure from experience that Potatoes do not exhauſt; but as ſoon as he perceives the bloom to be entirely gone; he gathers all the berries, and gives them to hogs, who devour them greedily[z].

Mr. Dann, who conſiders Potatoes as a more exhauſting crop than corn, allows that if cattle be fed with the produce, they would raiſe, with a moderate quantity of litter, dung ſufficient to manure nearly thrice the quantity of land the Potatoes grew on. This agrees nearly with Mr. Billingſley's opinion.

Notwithſtanding the general opinion is in favour of Potatoes, yet there are not wanting ſome who think that this culture muſt tend to impoveriſh every eſtate on which it is practiſed. Where this prevails reſtrictions and penalties are inſerted into leaſes, in ſome parts of the north of England. The opinions on this ſubject in Scotland are very various: indeed the accounts are very contradictory in moſt places. I ſhall not therefore enlarge upon them farther.

Mr. Marſhall ſettles the diſpute in this manner.—The Potato contains a great quantity of nouriſhment, and muſt therefore be a great exhauſter of the ſoil. It leaves it alſo in a ſingularly friable ſtate, cauſing an abundant produce of the crop that ſucceeds it. If therefore the huſbandman keeps cropping the land year after year with corn, and then, in its impoveriſhed ſtate lays it down to graſs, it is no wonder if it be unproductive. On the contrary, if after a crop of Potatoes well dunged for, only one or two crops of corn be taken, and the land laid down to graſs, whilſt yet in a ſtate of fertility, the Potato crop ſeems friendly to thoſe which ſucceed it.

The value of Potatoes as a fallow crop, and as an article of food for cattle compared with Turneps and Cabbages, may be conſidered thus. Potatoes are more nutritious, and ſeem to fat cattle quicker than either Turneps or Cabbages: being ſecured from the froſt, they are alſo a more certain article than the others, which occupy the ſoil in the ſpring, when it ſhould be prepared for the ſucceeding crop; whilſt Potatoes may be continued without inconveniency until the cattle be finiſhed, or the graſs has acquired its requiſite bite. Upon the whole, applying theſe to their proper ſoil: Cabbages are beſt for ſtrong tenacious land; Turneps for light ſhallow ſoils; and Potatoes for rich, deep, ſound, ſandy loams[a].

Crops following.

There is no doubt but the Potato crop is an excellent preparation for corn, provided the ground was well manured before, and duly hoed after the ſetting. The frequent ſtirring of the land by hoeing, and the complete opening of it by taking up the crop, muſt leave it in a looſe and friable ſtate, fit for the reception of ſeed. If the ſoil be a ſtrong loam or clay, Wheat may be ſown immediately with advantage; but on lighter loams, which are moſt proper for Potatoes, the land is commonly left in too looſe and friable a ſtate for Wheat, and on ſuch land it is generally more judicious to ſow Barley or Oats. Beſides, it frequently happens, eſpecially in cold expoſed ſituations, and in wet ſeaſons, that the Potato crop cannot be raiſed and got off the land before november, which protracts the ſowing of Wheat beyond the proper time.

Mr. Billingſley directs very judiciouſly. In a cold climate, and on a light ſoil, never ſow Wheat after Potatoes, but ridge up your land, and leave it for a ſpring crop; and perhaps on any ſoil it is good huſbandry ſo to do. As a trial, he ſowed half of fifty acres with Wheat in the beginning of november; the other half he ſowed with white Oats in april: the latter was uncommonly fine, and the Wheat very indifferent[b].

In Eſſex however, about Ilford, their autumnal crops of Potatoes are ſucceeded by Wheat, which is generally fine; and the ſummer ones by Turneps. They mow Clover, and plough it up the beginning of july, and plant immediately[c].

Mr. Pitt of Pendeford found his Wheat crop always equal to what might have been expected after any other preparation, but perhaps the Wheat ſtubble not ſo clean or kindly as after fallow Wheat[d].

Mr. Culley of Fenton in Northumberland, does not remember ever to have had a bad crop of Wheat after Potatoes, or indeed of any corn; and generally the grain good in quality[e].

Mr. Dann ſowed an acre and half with Wheat after Potatoes, in october, with only one ploughing and no freſh manure. The produce eight quarters and a half of clean corn. The land was full of Quick and other weeds, and was well cleaned by the Potato crop[f].

Mr. Hunter of Gubbins ſowed thirty-eight acres of Wheat after Potatoes, with the drill-plough, a buſhel and half of ſeed to the acre[g].

Mr. Barbor ſays his land after Potatoes was in excellent order for Wheat, and that he had a better crop than ever was ſeen in his neighbourhood[h].

Mr. Kingſton of Oak-hill near Barnet, ſays that his ground was in fine dry condition for dibbling in Wheat, which in january looked exceedingly healthy and fine, and took only a peck and half of ſeed to the acre[i].

Mr. Harper of Bank-Hall, in Kirkdale, Lancaſhire, ſays that if Potato land be laid dry, and remain ſo for the winter, it will be equal to Turnep land, for any ſpring crop that the land will bear: but that it is moſtly ſown with Wheat, let the ſeaſon turn out ever ſo bad; and by being ſown in bad condition, it commonly leaves the land foul. In this caſe Mr. Harper never ſows Wheat, but always finds his land in excellent order for an early ſpring crop[k].

At Slaine in Ireland Wheat is ſown after Potatoes, ſometimes Barley; the latter good, but the Wheat

generally

Digitized by Google

generally a bad crop and bad grain. Hence Mr. Young ſuppoſes the ſoil to be ſo light as to require adheſion to be given it.—About Furneſs they ſometimes ſow Wheat after Potatoes, and the crops are as great as after fallow; but the quality of the grain is inferior [l].

Mr. Young, in his directions for the management of land, recommends the following courſe of crops: 1. Potatoes. 2. Wheat. 3. Turneps. 4. Barley. 5. Clover. 6. Wheat. The ſeed wheat ready brined and limed to be in the field, and the ſeedſman with his baſket; as ſoon as the ploughman turns a furrow, the ſeedſman follows him cloſe, throwing the ſeed not into the furrow juſt opened, but on the land thrown over by the plough, the forkmen then divide themſelves at equal diſtances along it, and ſhaking the mould, which the ploughman turned over, with their forks, the boys pick up the Potatoes. The forkmen muſt leave the land regular without holes, for there is to be no other tillage for the Wheat [m].

For any ſoils, except ſtrong ones, another courſe is: 1. Potatoes. 2. Flax. 3. Clover. 4. Wheat. In this courſe, the land is left till ſpring; no water being ſuffered to ſtand on it in the winter. In the ſpring more or fewer ploughings to be applied, as will beſt inſure a fine friable ſurface to ſow the Flax in [n].

Mr. Young remarks, that the firſt of theſe courſes is upon the whole the moſt profitable that can be practiſed on all ſoils that will do for the two roots. Becauſe one third of the arable land is every year in Wheat. It contains ſpring corn, the ſtraw of which is neceſſary for cattle. The Turneps do for the ſheep, and the Clover will feed in ſummer the ſtock hogs, ſupported in winter by the Potatoes; with this great advantage that the two crops of Wheat are put in at ſcarce any expenſe, and that there is no other expenſe on the Potatoes than mere ſetting, ſince all the reſt is done in order to take up that crop [o].

He has truſted to Potato crops as a fallow, previous to laying down to meadow, which demands as clean a fallow as any object poſſibly can. The ſeeds were ſown with Barley [p].

Mr. Lodge of Great Blakenham in Suffolk, ſays he is certain no crop leaves the land ſo clean as Potatoes, and that he uſually ſows Barley after them with good ſucceſs. He intends trying the following courſe: viz. Potatoes in rows thirty to thirty-ſix inches apart; then winter Tares, with Barley or Rye, mown in june or the beginning of july for Hay; the land trench-ploughed for Turneps; the third year Barley with Clover; followed by Wheat. Thus every fifth year he purpoſes having a crop of Potatoes, upon which he ſhall beſtow all the dung he can muſter. He has tried Wheat after Potatoes, but not with ſuch good ſucceſs as Barley; believing that they leave his land too light and porous for Wheat [q].

Mr. Young remarks on Mr. Billingſley's reſult given above, that it unites entirely with his own experience, for that he never got a good crop of Wheat after Potatoes; and that it is owing to two circumſtances; firſt, the ſoil is too much pulverized; 2dly, the root exhauſts ſo much as not to leave nouriſhment ſufficient for Wheat [r].

Mr. Robinſon of Steeple-Langford, Wilts, has ſeveral times ſown, and often obſerved other people's Wheat after Potatoes, and there was invariably a thin crop of ſtraw, and a poor ſhrivelled grain: Barley and Oats are as invariably good [s].

Mr. Walker of Norfolk, upon a clean Turnep fallow, planted Potatoes under the plough in june, and harrowed in Turnep ſeed above them, timing it ſo that the Turneps and young Potato ſhoots ſhall come to the hoe at the ſame time. He feeds the Turneps off early in autumn, and then ploughs the land for Wheat; gathering the Potatoes at the ſame time. He has had a full crop of Turneps, and 120 buſhels of Potatoes on an acre [t].

Mr. Bell of Dumfrieſſhire drills Potatoes at four feet and a half; and the hoeing being over by the end of june, he drills Turneps in the intervals [u].

Mr. Hollins of Montgomeryſhire, after the rows of Potatoes were covered, with a ſtick ſet beans along the middle of the rows; both grew up together very well, and came to perfection, without injuring each other in the leaſt [x].]

Tomatos.

32, 33, 34, 35, 36, 37, 38, 40. Theſe plants are all propagated by ſowing their ſeeds on a moderate hot-bed in march, and when the plants are come up two inches high, they ſhould be tranſplanted into another moderate hot-bed, at about four inches diſtance from each other, obſerving to ſhade them until they have taken root; after which they muſt have frequent waterings, and a large ſhare of freſh air; for if they are too much drawn while young, they ſeldom do well afterwards.

In may theſe plants ſhould be tranſplanted either into pots filled with rich light earth, or into borders near walls, pales, or Reed-hedges, to which their branches may be faſtened to ſupport them from trailing on the ground, which they otherwiſe will do, and then the fruit will not ripen; ſo that where theſe plants are cultivated for the ſake of their fruit, they ſhould be planted to a warm aſpect, and the branches regularly faſtened as they extend, that the fruit may have the advantage of the ſun's warmth to forward them, otherwiſe it will be late in the ſeaſon before they are ripe, and they are unfit for uſe before; but when the plants are brought forward in the ſpring, and thus regularly trained to the ſouth ſun, the fruit will ripen by the latter end of july, and there will be a ſucceſſion of it till the froſt kills the plants.

Some perſons cultivate theſe plants for ornament, but their leaves emit ſo offenſive an odour on being touched, as to render them very improper for the pleaſure-garden, and their branches extend ſo wide and irregular, as to render them very unſightly in ſuch places; for as their branches cannot be kept within bounds, eſpecially when they are planted in good ground, ſo they will appear very unſightly in ſuch places; therefore the borders in the kitchen-garden, where theſe plants are placed for their fruit, muſt not be too rich, for in a moderate ſoil they will not be ſo luxuriant and more fruitful.

The Italians and Spaniards eat the fruit of the Lycoperſicum (n. 33.) as we do Cucumbers, with pepper, oil, and ſalt; and ſome eat them ſtewed in ſauces, &c. and in ſoups they are now much uſed in England. This fruit gives an agreeable acid to the ſoup, though there are ſome perſons who think it not wholeſome, from the great moiſture and coldneſs, and that the nouriſhment it affords muſt be bad.

The other ſorts are never uſed either in the kitchen or for medicine, but the plants are preſerved for the ſake of variety, eſpecially by thoſe perſons who are lovers of botany. The 40th ſort is propagated by ſeeds, which ſhould be ſown upon a hot-bed in the ſpring, and the plants afterwards treated in the ſame manner as has been directed for the Capſicum, with which this plant will thrive and produce plenty of fruit annually.

39. Garden Nightſhade is a common weed on dunghills and in gardens. That and all the varieties are annual, and are propagated by ſowing their ſeeds in the ſpring, on a bed of rich earth, where the plants are deſigned to remain. When they come up, thin them to at leaſt two feet diſtance. In july and auguſt they will flower, and the ſeeds will ripen in autumn. A plant or two of the more tender varieties may be ſet in pots and trained to ſticks; to be removed into the greenhouſe in autumn. During the winter, when the fruit is ripe, they will make a pretty appearance.

41. 45. The different ſorts or varieties of Melongena or Egg Plant are propagated by ſeeds ſown upon a moderate hot-bed in march. When the plants come up, tranſplant them into another hot-bed about four inches aſunder, obſerving to water and ſhade them

until they have taken root; after which give them a a great ſhare of air, when the weather is warm. Water them frequently, and when they fill the frame, which will be by the middle or end of may, tranſplant them into a rich ſpot of ground, at two feet diſtance, or into the borders of the pleaſure garden, preſerving a good ball of earth to the roots. Water them plentifully till they have taken root. About the middle of july the fruit will appear; and then, if the weather be dry, water the plants often, to increaſe the fruit in number and ſize: in auguſt it will ripen, in hot countries it is eſteemed a delicacy, but in England it is merely regarded as a curioſity.

42. 43. 44. 46. 47. 48. 49. 52. 53. 54. 59. 60. 63. 66. 67. 69. 70. 71. 72. 73. 75. 76. 77. 78. 79. 80. 81. 82. 83. 88. 89. 90. 91. 92. 93. All theſe being natives moſtly of the Weſt Indies, and ſome of the Eaſt Indies, muſt be raiſed from ſeeds on a hot-bed early in the ſpring. When the plants are fit to remove, put each in a ſeparate ſmall pot filled with freſh rich earth; plunge them in a moderate hot-bed of tanner's bark, and ſhade them from the ſun until they have taken new root; after which admit a large ſhare of freſh air to them in warm weather, and water them frequently. Towards the end of june harden them gradually; and ſoon after remove them into the ſtove, where they muſt have as much free air as poſſible in warm weather; but as the cold approaches in autumn, they muſt be carefully protected, and in winter they muſt be kept in a moderate temperature of warmth. Some of theſe will bear to be expoſed to the open air in the heat of ſummer, in a warm ſituation; but in general it is better to let them remain in the ſtove, with the glaſſes open in front; and every day, in warm weather, to admit as much air as poſſible at the top of the ſtove.

DESCRIPTION, *&c.*

Root perennial, fibrous. Leaves almoſt kidney-ſhaped, about three quarters of an inch over each way, of a dark green colour, on long foot-ſtalks. Among theſe ariſes a naked flower-ſtalk or ſcape, about four inches long, ſuſtaining at the top two ſmall open bell-ſhaped flowers, with the brim cut into many fine ſegments like a fringe: the moſt frequent colour is blue, but it is ſometimes ſnow-white. It flowers in april, and the ſeeds ripen in july.

[The largeſt ſpecimen, ſays Scopoli, that I poſſeſs, has the leaf eleven lines long, and an inch broad, emarginate at the baſe, on a petiole near two inches in length. Scape a ſpan high, terminated by three flowers, the middle one longer. (Haller ſays, that the flowers are from one to three.) Corollas blue with ſome mixture of red, moderately nodding. Capſules erect, much reſembling thoſe of Ceraſtium arvenſe: (according to Haller, deep blue, like the flower.) Receptacle on a columnar peduncle a line in length. Seeds roundiſh, as many as ſixty.

Native of the Alps of Switzerland, Auſtria, Bohemia, Dauphiné, Piedmont. Cultivated in 1656, by Mr. John Tradeſcant[y].

Gerarde ſays it grows wild in North Wales, but it has not been found there ſince his time.

β. This has all the parts ſmaller; the petiole is ſhorter and more ſlender, and the leaves are not ſo much rounded, but gradually widen from the petiole[z].

Cluſius found this variety in 1578.]

PROPAGATION AND CULTURE.

Part the roots in ſeptember. If removed in ſpring, the plants never flower ſtrong; and if the ſeaſon ſhould prove dry, they will decay, unleſs they are conſtantly ſupplied with water. The ſeeds ſeldom grow unleſs they are ſowed ſoon after they are ripe; for which reaſon thoſe ſent from abroad ſeldom ſucceed.

This plant thrives beſt in a ſtrong cool loam, and muſt have a ſhady ſituation: expoſed to the ſun it will not live; nor will it thrive in a warm light ſoil. In dry weather it ſhould be frequently watered.

[The Soldanella requires, like moſt other alpine plants, ſhade and moiſture in the ſummer, and thrives beſt in a pot, ſet in a northern aſpect: in winter, it requires the ſhelter of a frame, in lieu of ſnow, its more natural covering[a].]

Seeds that ripen in England, may be ſown in a box or pot, ſoon after they are ripe, placed in the ſhade, and frequently watered in dry weather. The plants will ſometimes appear in autumn, but more frequently not till the following ſpring. When they come up, they muſt be duly watered in dry weather, and kept conſtantly in the ſhade. The following autumn, tranſplant them into a ſhady border ſix or eight inches aſunder; [or rather into ſmall pots.

Stem ſhrubby, leaves lanceolate ſmooth quite entire, flowers corymbed terminating.

DESCRIPTIONS, *&c.*

[The Golden-rods are natives of North America, except two ſpecies which are fouud in Europe, and two others which were diſcovered by Houſtoun in New Spain, and have not been adopted by Linneus or any other author. I have generally followed the catalogue of the Royal Garden at Kew in the determination of the ſpecies, and the ſpecific characters, which were probably reformed by the late Dr. Solander. Moſt of the ſpecies are there ſaid to have been cultivated by Mr. Miller in 1758, which was the year when Mr. Aiton came to the Chelſea garden: many of them however had been there long before, certainly ss far back as 1731, and ſome even in 1699. They were very imperfectly diſtinguiſhed by Linneus. The flowers are yellow, and frequently in long ſpikes, whence the names of *Virga aurea* and *Golden-rod.*

1. Linneus only remarks upon this ſpecies, that the leaves are narrow-lanceolate, ſcarce apparently ſerrate, and almoſt ſmooth.

Mr. Miller makes two ſpecies of this—*canadenſis* and *humilis*. The firſt he deſcribes as having] the ſtalks round, ſmooth, and two feet high; the leaves narrow and rough, with three longitudinal veins, two inches and a half long, and a quarter of an inch broad in the middle, ſeſſile, ending in acute points, and having ſometimes a few ſlight ſerratures: the flowers in a roundiſh terminating panicle, the lower ſpikes of which are reflexed, but thoſe at the top erect and joined very cloſe; theſe appear in july.

The ſtalks of the ſecond are very ſtrong and near two feet high; very cloſely garniſhed with narrow, ſpear-ſhaped, ſtiff leaves, four inches long, and half an inch broad, a little indented on their edges and ſeſſile. The flowers are diſpoſed in large panicles at the top of the ſtalks: the ſpikes are long, recurved, and compoſed of ſmaller ſpikes in cluſters: they appear in ſeptember.

[A third variety is added in the Kew catalogue, the leaves of which are hairy underneath, and the upper ones quite entire. The common Canadian Golden-rod has been long known in our gardens, having been cultivated in 1656, by Mr. John Tradeſcant, junior [b].]

2. This ſeems to be the *hirſutiſſima* of Miller, which he ſays grows naturally in Canada. The ſtalk is ſtrong and hairy, five or ſix feet high, cloſely gar-

[b] Hort. kew.

niſhed

Digitized by Google

niſhed with rough ſpear-ſhaped leaves ending in acute points, four inches long, and one broad, very hairy on their under ſide, ſharply ſerrate, and having three ſtrong longitudinal veins: the flowers are diſpoſed in a roundiſh panicle at the top of the ſtalk; the ſpikes are recurved; the flowers are ſmall and of a brimſtone colour; they appear in ſeptember, and frequently continue to the end of october.

[3. I cannot affix any of Mr. Miller's ſpecies to this, though he certainly cultivated it. The copious ſpecific character is ſufficient to diſtinguiſh it.

4. 5. The caſe is the ſame with theſe two ſpecies.

6. Plant, according to Linneus, ſmaller than *S. canadenſis*. Leaves not ſerrate, ſofter, but ſometimes having one or two teeth. Flowers and all things as in the preceding, but the ſtem below the middle puts out ſimple branches, a little ſhorter than the ſtem, corymboſe at the top but no branches between the terminating corymb of the ſtem and the middle or branches, which is ſingular in this ſpecies. The deſcription affixed to fig. 1. of plate 254. in Mr. Miller's figures, ſeems to agree with the ſpecific character of this ſpecies, as given in the Kew catalogue: but I dare not ſay that they are the ſame.—Stalk upright, ſmooth, near three feet high. Leaves ſmooth, ſpear-ſhaped, ending with acute points, about three inches long, and an inch broad in the middle, of a light green colour. The upper part of the ſtalk branches out into a panicle, and theſe branches have long ſpikes of flowers coming out from their wings, which are recurved: the flowers are ranged on one ſide of the foot-ſtalk, and ſtand erect; they are of a bright yellow, and have five or ſeven florets in the ray. It flowers at the beginning of auguſt, and if the autumn proves favourable, the ſeeds will ripen at the end of ſeptember. Native of New Jerſey, whence the ſeeds were ſent to Mr. Miller in 1756, by Mr. John Bartram.

In the ſame plate (fig. 2.) another ſpecies is repreſented, which in the Dictionary (n. 27.) he calls *conferta*. I cannot refer it to any of the ſpecies in Linneus or the Kew catalogue.—He thus deſcribes it:] Stalks branching, from three to four feet high. Leaves ſmooth; the lower ones ſpear-ſhaped, oblique, entire, five inches long and two broad in the middle, on long footſtalks. The axillary ſpikes of flowers are long, blunt, and a little recurved at the end: thoſe on the upper part of the ſtalk are erect, and cluſtered together in a cloſe ſpike; they appear in ſeptember.—Native of Philadelphia, whence the ſeeds were ſent to Mr. Miller by Dr. Benſel. The ſeeds, in warm ſeaſons, will ripen in England.

[The Kew catalogue diſtinguiſhes two varieties of the *lateriflora*: one with red ſtalks ſcarcely hairy; the other with green hairy ſtalks.

7. Stems three feet high, the thickneſs of a ſtraw at the baſe, round, hairy, finely ſtreaked, clothed with leaves from top to bottom, diminiſhing gradually in ſize upwards, ſerrate, hirſute and rough, hairy along the nerve and veins at the back, deſtitute of hairs on the upper part, rough at the edge to the touch, of a ſomewhat paler colour underneath. At a foot or a foot and half from the top the ſtem puts out branches, which are very full of ſmall flowers, on ſpikes a little reflexed.

Native of Virginia and Carolina. It flowers here in ſeptember [c]. Cultivated in 1732, by James Sherard, M. D.[d].

This is a ſmaller plant than the next; the leaves are ſhorter and ſomewhat wider, of a darker green, and ſerrate almoſt to the top; the flowers are in more numerous ſpikes, and appear a little later [e].

8. Stems numerous, ſtraight, rigid, from three to four feet and a half high, the thickneſs of a ſtraw or more at the baſe, round, ſlightly ſtreaked, hirſute, clothed from top to bottom at ſhort diſtances with leaves, which are widiſh, oblong, pointed, rough, at their upper and lower parts thinly crenate, in the middle ſerrate, the ſerratures minutely crenate; thoſe on the upper branches not ſerrate, but only minutely crenate; they are green on both ſides, with a few oblique veins, and are hairy along the nerve and veins at the back, but without hairs every where elſe. Flowers very many, on the upper branches, in long rod-like ſpikes, ſomewhat reflexed; having four, five or ſix florets in the ray. They appear in auguſt and ſeptember.—Native of New England, Virginia and Carolina [f].

Linneus ſays, it has the habit of the *canadenſis*, but differs in the ſize, ſerratures and nerves of the leaves: and that it unites ſpecies ſcarcely genuine, perhaps mules, of which the limits can ſcarcely be diſtinguiſhed. He recommends therefore a compariſon of ſeveral which he names.

Mr. Miller has made ſeveral ſpecies out of this.]

1. *S. altiſſima*: the ſtalks of which are round and ſmooth, above four feet high: the leaves rough, acute-pointed, and without veins; cloſer together on the ſtalks, and ſhorter and broader than thoſe of *canadenſis*: the panicles of flowers are much larger, the ſpikes much longer, ſpreading out wider, and more reflexed.

2. *S. piloſa*: the ſtalks of which are round and hairy; near three feet high, cloſe garniſhed with rough ſpear-ſhaped leaves, two inches long, and half an inch broad, ſlightly ſerrate, and ſeſſile. Flowers from the axils at the upper part of the ſtalk, in long recurved ſpikes, ſmall, ſulphur-coloured, on ſhort footſtalks, appearing at the end of july.

3. *S. recurvata*. Stalks hairy, branching towards the top. Leaves ſpear-ſhaped, rough, ſeſſile; the lower ones four inches long, and an inch and half broad; on the ſtalks gradually diminiſhing in ſize to the top; rough, veined and ſerrate. Flowers in a terminating panicled corymb; the ſpikes on the lower part recurved, but at the top cluſtered and erect. They appear in ſeptember and october. Native of Philadelphia.

4. *S. virginiana*. Stalks round, channelled, two feet high. Leaves rough, acute-pointed, ſerrate, two inches and a half long, and an inch broad. Flowers in a terminating panicle: ſpikes very long, recurved, and ſpreading out on every ſide; the lower parts of the branches cloſely furniſhed with ſmall leaves, and the flowers in cloſe cluſters at the end of the ſpike: they are of a bright yellow, and appear late in ſeptember. Native of Virginia.

5. *S. rugoſa*. Stalks round, hairy, two feet and a half high; the upper branches in a looſe panicle. Leaves ſeſſile, rough, ſpear-ſhaped, entire; the lower ones two inches long, and half an inch broad, but gradually ſmaller to the top. Spikes of flowers axillary: the lower ones long, but diminiſhing to the top. The branches have many ſmall leaves growing along them, ſome of which are intermixed with the flowers; which appear in the middle of november. Native of New England.

[9. This was introduced in 1769, by Samuel Martin, M. D. and flowers in ſeptember.

10. Cultivated by Mr. Miller in 1758. It flowers in july and auguſt.

11. Introduced in 1769, by Samuel Martin, M. D. It flowers in auguſt and ſeptember. Theſe are all natives of North America [g].]

12. Stalks ſtiff, round, ſmooth, with a white bark, upwards of three feet high. Leaves ſpear-ſhaped, ſmooth, with ſeveral veins, three inches and a half long, and one inch broad, alternate. Flowers from the upper axils, in ſhort, erect, obtuſe ſpikes, of a pale yellow colour, and appearing in auguſt. Native of Canada.

13. [This is remarkable, ſays Linneus, for its red ſtalk, higher than a man, with very ſmooth and ſomewhat fleſhy leaves, a little rugged at the edge, continuing the whole winter; it flowers very late, ſo that in Sweden the froſt commonly prevents them from opening.

Linneus did not diſtinguiſh this from the *lævigata*. Miller ſeems to have intended the *ſempervirens* by his *glabra*, which he thus deſcribes.] The lower leaves are fleſhy, narrow ſpear-ſhaped and entire: the ſtalks ſmooth, purpliſh, near three feet high, garniſhed with long, narrow, ſmooth, keel-ſhaped entire leaves: the

[c] Dillenius. [d] Hort. kew. [e] Dill. hort. elth. [f] Idem. [g] Hort. kew.

flowers

Digitized by Google

flowers are diſpoſed in a looſe panicle at the top of the ſtalk; the ſpikes are ſlender and erect; the flowers of a bright yellow, appearing late in october, and ſometimes continuing till december.

Native of North America. [Linneus ſays New York and Canada, we may add Virginia, if this be Gronovius's plant.—It was cultivated in 1699 by the Dutcheſs of Beaufort.

14. Cultivated in 1763, by Mr. James Gordon. It flowers in july and auguſt [h].

15. Stem five feet high. Leaves long, rugged eſpecially at the edge. Calyxes ſmall, obovate, ſubſquarroſe. Ray of the corolla ſmall [i]. It is deſcribed at length in Linneus's ſpecies under the name of *Chryſocoma graminifolia*. Unleſs this is the *noveboracenſis* of Miller, I know not where to fix it. He thus deſcribes that ſpecies.] The lower leaves are long, narrow, and very ſmooth, keel-ſhaped and entire. Stalks red, fleſhy, ſmooth, two feet high, thinly garniſhed with narrow, ſmooth leaves. Flowers in looſe panicles at the top of the ſtalks, and ſome ſingle ſpikes from the axils below. Flowers bright yellow, appearing in auguſt. Native of New England, [and other parts of North America.

16. Stalks thick, fleſhy, of a purpliſh colour, frequently ſix feet high in good ground. Leaves ſpear-ſhaped, thick, fleſhy, of a deep green colour, and very ſmooth; but their edges are a little rough to the touch; they are ten inches long, and an inch and half broad, drawing to a point at each end. The flowers terminate the ſtalk in a roundiſh panicle or corymbus. The common calyx is longer than in moſt of the other ſpecies, and the ſcales are ſmoother; the radial florets are much narrower in proportion to their ſize; the florets of the diſk are large, and their ſegments not ſo acute. It is a native of many parts of North America, but was firſt brought to Europe from Canada. It ſeldom ſhows its flowers till late in october, ſo that unleſs the autumn proves favourable, the ſtalks are pinched by the froſt before the flowers blow. The ſeeds ſcarcely ever ripen in England, unleſs the plants are ſheltered [k].

This ſeems to be what Linneus intended by his *ſempervirens*. There is no doubt of its being the *carnoſa* of Miller.

Moriſon ſays it is a taller plant, and has wider thicker leaves than our *ſempervirens* (n. 13.) They both flower in the ſame manner; the ſtems with the leaves and flowers continue the whole winter, and they were cultivated in the Chelſea garden in 1699, when the third part of his work was publiſhed [l].]

17. Stalks oblique, a foot and half high, ſmooth, with a brown bark. Leaves ſmooth, ſpear-ſhaped, entire, three inches long, and three quarters of an inch broad. The flowers come out on branching foot-ſtalks on the ſide of the ſtalks, are ranged on one ſide, and have a few ſmall leaves under the flowers; which appear at the end of auguſt.

[Native of North America. Cultivated in 1697, by the Dutcheſs of Beaufort [m].

Caſpar Bauhin called it *Virga aurea Mexicana*, having been told probably that it was a native of Mexico; Mr. Miller has adopted this error; Linneus doubted it. Bauhin had it from Spoerlin, who gathered it in Robin's garden at Paris.]

18. Stalks ſmooth, erect, a foot and half high. Leaves narrow, ſmooth, entire, dark green. Flowers in cloſe compact panicles at the top of the ſtalk; ſpikes ſhort, cluſtered. Flowers large, bright yellow, appearing in ſeptember.

Native of North America. [Cultivated by Mr. Miller in 1759.

19. 20. Natives of North America, and cultivated by Mr. Miller in 1758. The former flowers in ſeptember; the latter from october to december [n].

Mr. Miller has a ſpecies which he names *S. petiolata* (n. 29.) But it can ſcarcely be the ſame with the *petiolaris* of the Kew catalogue. He deſcribes it as having] the lower leaves ſmooth, entire, narrow and ſpear-ſhaped, three inches and a half long, and half an inch broad, ſtanding upon long foot-ſtalks: the ſtalks round, ſmooth, three feet high, having very ſmall, ſmooth, entire, ſeſſile leaves on them: the flowers in a cloſe panicle at the top of the ſtalk, of a bright yellow, and appearing in ſeptember. Native of Philadelphia.

21. Lower leaves oval, ſix inches long, and three broad, ending in acute points, ſerrate, having ſeveral ſtrong longitudinal veins on long foot-ſtalks which have leafy borders or wings. Stalks a foot and half high, branching out almoſt from the bottom, garniſhed with ſmall, ſpear-ſhaped, entire leaves. The branches grow erect, are cloſely furniſhed with ſmall leaves below, and are terminated by ſhort cloſe ſpikes of white flowers; [or rather, having a yellow diſk and a white ray, in cloſe racemes [o].

Native of North America. Cultivated by Mr. Miller in 1759. It flowers in ſeptember [p].]

22. Stalks two feet high. Lower leaves ovate, ſtiff, ſmooth and entire, four inches long, and two inches and a half broad, on foot-ſtalks four inches in length: thoſe on the upper part of the ſtalk are ſpear-ſhaped, entire, and embrace the ſtalk half round. Flowers in looſe, ſpreading, terminating panicles; ſpikes ſhort, cluſtered, roundiſh; bright yellow, appearing in auguſt.

Native of New England. [Cultivated in 1759, by Mr. Miller [q].]

23. Stalk ſlender, ſmooth, a foot and half high. Leaves narrow-ſpearſhaped, two inches long, and half an inch broad, indented on their edges, and ending in acute points. Flowers in a looſe terminating panicle, with the ſpikes cloſer and thicker towards the top.

[According to Dillenius, the ſtems are three feet high, ſtiff, round, ſmooth, without ſtreaks, gray, but purpliſh towards the top, dividing into many branches. Leaves tender, thin, ſmooth, glaucous, pale grayiſh-green underneath.

Native of Maryland, whence it was procured and ſent to the Eltham garden by Peter Collinſon. It flowers in ſeptember.]

24. The lower leaves are four inches long, and almoſt two broad; their foot-ſtalks are two inches long, and have a membrane or wing on each ſide. The ſtalks riſe two feet high; they are ſlender, ſmooth, and of a light purple colour. Leaves ovate-lanceolate, indented, near two inches long, and three quarters of an inch broad, of a pale green on their under ſide. The flowers are produced in ſhort bunches from the axils almoſt the whole length; the lower ſpikes are an inch long, but the upper ones are almoſt round. The flowers are of a brimſtone colour, and appear late in auguſt.

[Linneus has made two ſpecies out of this, which he names *flexicaulis* and *latifolia*. The latter, he ſays, is too nearly allied to the former: the ſtem ſtraight, (whereas the other is flexuoſe or winding,) and acutely angular: the leaves ovate, mucronate both ways, ſerrate, ſmooth above but rugged beneath: racemes from the wings, commonly ſhorter than the leaf.

Native of Canada,—and other parts of North America. Cultivated by Mr. Miller in 1731 [r].

25. This is ſaid in the Kew catalogue to have been cultivated by Mr. Miller in 1759; but we are not informed there which ſpecies of the Dictionary is intended. I know not which it is, unleſs it be the *ſcrophularifolia*, *n.* 12. He thus deſcribes it:] Stalks ſlender, ſmooth, two feet high. Leaves ovate, acuminate, ſerrate, three inches long and two broad, alternate at two inches diſtance. Flowers in long bunches from the axils, diſpoſed looſely, and pale yellow; appearing in auguſt, and continuing part of ſeptember.

26. [Root perennial, of long ſimple fibres. Stem very various in height, from ten inches to three feet, commonly branching into a panicle, more or leſs flexuoſe, never entirely ſtiff and ſtraight, leafy, angular, ſtriated, a little downy; at the baſe round and often purple. Leaves elliptic-lanceolate, ſomewhat rugged, and ſtiffiſh; thoſe next the root wider, on longer petioles,

Digitized by Google

petioles, and more widely ſerrate; ſtem-leaves for the moſt part indiſtinctly crenate-ſerrate, ſometimes almoſt quite entire, varying in ſize, often recurved; the upper ones gradually diminiſhing into lanceolate downy bractes: all ſomewhat hairy, or covered with ſhort ſtiff down, paler underneath: footſtalks winged. Flowers in terminating and axillary erect cluſters of corymbs, forming a denſe leafy pubeſcent panicle, which varies extremely as to luxuriance and number of flowers; in a barren ſoil and on mountains being ſhorter, more denſe and leſs compound. Corolla of a golden colour. Calyx-leaves finally patulous, but all ſtraight, lanceolate, ciliate, ſometimes rugged at the back, having a membranous border. Florets of the ray from five to nine or ten, ſpreading, elliptic-oblong, toothed at the top. Seeds pubeſcent. Seed-down appearing rugged when magnified [s].

On heaths it frequently does not exceed a foot in height; but in hedges and coppices it is three or four feet high, unbranched. Lower leaves ovate-lanceolate, tapering into the footſtalk, diſtantly ſerrate but almoſt entire at the ſummit, rough, ſlightly hairy, dark green above, glaucous beneath, reticulated with numerous veins; upper leaves alternate, almoſt ſeſſile, lanceolate, entire or nearly ſo. Numerous flowering-branches ariſe from the axils of the leaves; lower ones ſhorter, upper longer than the leaves, bearing ſix or eight flowers, or branched peduncles, with each one or two ſmall bracteal ſcales. Calyx imbricate with unequal lanceolate ſcales, having a green dorſal line, and whitiſh ſhining membranaceous edges. Seeds brown, convex on one ſide, plane on the other, hairy the whole length, nearly as long as the calyx, crowned with a ſeſſile ſimple down [t]:—ſmall, oblong, tapering downwards, round or indiſtinctly angular, beſet with very minute briſtles: down capillary, remotely toothletted, half as long again as the ſeed. Receptacle narrow, flat, naked, full of ſmall excavations, and rugged with their toothletted margins [u].

Native of Europe, Siberia, and Japan, in woods, coppices, hedges and heaths; flowering from july to ſeptember.

It has been ſuſpected that our Engliſh Golden-rod is different from the *S. Virgaurea* of Linneus; but we are aſſured by Dr. Smith, whoſe authority is deciſive, that on a careful compariſon of ſpecimens, they are found to be preciſely the ſame.

The herb when bruiſed ſmells like wild Carrot. It has been eſteemed a vulnerary, and is recommended to be taken internally, as well as applied to the wound. As a tonic it may ſtrengthen the general habit, and by that means be of uſe [x]. A caſe is related in the Gentleman's Magazine for february 1788, of the efficacy of a decoction made with this plant, in the ſtone. A boy ten or eleven years of age, after taking a decoction or infuſion of the Golden-rod for ſome months at times, voided great quantities of gravel, with many ſmall ſtones, and after that fifteen larger ſtones from three fourths of an ounce to an ounce and quarter, beſides fifty or more not leſs than a large pea.—It is celebrated in old authors for its lithonthriptic qualities, ſome more modern ones allow them, but it is entirely diſcarded from our regular practice. In my remembrance, ſays Gerarde, the dry herb which came from beyond the ſea ſold in Bucklerſbury for half a crown an ounce; but ſince it was found in Hampſtead wood, no man will give half a crown for an hundred weight of it.

From its vulnerary qualities, it is called in ſome places *Woundwort*, which is a name given to many other plants, for the ſame reaſon; others call it *Aaron's rod*.

Mr. Miller has made five ſpecies from the varieties of the European Golden-rod.] 1. Not common in England, but grows plentifully in Brabant, and is the moſt common in Germany. Stalks ſtiff, purpliſh brown, two feet high. Panicles axillary and terminating, each flower on a long ſlender foot-ſtalk, pale yellow, appearing at the beginning of auguſt. Leaves lanceolate, almoſt four inches long, and a quarter of an inch broad, deeply ſerrate, pale green beneath. This is our β. and the broad-leaved Golden-rod.

2. Our common Golden-rod about London. (α.) Lower leaves ovate-lanceolate, two inches long and an inch broad, ſlightly ſerrate, on pretty long foot-ſtalks. Stems ſlender, a foot and half high; with ſmall, narrow, entire, ſeſſile leaves. Flowers in panicled bunches, cluſtered together, forming a thick, erect ſpike; appearing in auguſt and ſeptember.

3. Narrow-leaved Golden-rod. (γ.) Frequent in ſeveral parts of England, as in the woods near Dulwich in Surry. Stalk round, ſmooth, a foot and half high. Leaves narrow-lanceolate, an inch and quarter long, and an eighth of an inch broad, almoſt entire, ſeſſile. Flowers in ſmall cluſtered bunches from the axils, to which they ſit very cloſe; and the ſtalk is terminated by a roundiſh bunch. The flowers being produced at every joint on the upper half of the ſtalk, the ſpikes being ſhort, do not make ſo good an appearance as thoſe of the ſecond.

4. Dwarf Golden-rod (δ.) grows in the woods at Hampſtead, whence Mr. Miller ſeveral times tranſplanted roots into the garden, where they continued many years without varying. Lower leaves indented. Stalk ſeldom more than a foot high, branching out almoſt from the bottom. Branches terminated by ſhort, cluſtered, erect ſpikes. Leaves on the ſtem and branches very narrow, acute-pointed and entire.

[Whether this be the ſame which was gathered by Sherard in Ireland, I cannot ſay. That is deſcribed, as having the leaves narrower and ſlightly ſerrate, on long petioles; and the flowers larger, from the axils, collected into a ſort of ſpike [y].

In all theſe varieties, the degree of ſerrature on the leaves, as well as the length of the leaf-ſtalks, is very variable; but the ſtem in all is ſerpentine (flexuoſe,) ribbed and cottony [z].]

5. Welch Golden-rod (ε.) has the lower leaves narrow-lanceolate, an inch and half long, and a quarter of an inch broad, ſmooth, ſlightly ſerrate, a little hoary on the under ſide. Stalk about ſix inches high, with the ſame ſort of leaves on it, only ſmaller. Flowers in roundiſh cluſtered terminating ſpikes, much larger than thoſe of the common ſort, and appearing five or ſix weeks earlier.

[This is a well-marked variety, but can ſcarcely be reckoned a diſtinct ſpecies, though it is ranked as ſuch, not only by Miller, but by Hudſon, Withering and Aiton. In the work of the latter it is diſtinguiſhed by its very ſimple pubeſcent ſtem; wedge-lanceolate ſerrate and ſomewhat hairy leaves, upright racemes, and elongated ligules.

According to Dr. Withering, it is from three to ſeven inches high. The flowers ſometimes form a corymbus, ſometimes a compact ſpike-like bunch, but the ſecondary fruit-ſtalks do not ſeem to be ever branched, as they are in the common Golden-rod. When cultivated, it attains the height of eighteen inches or more, but ſtill preſerves its ſtraight unbranched ſtem, and its great length of leaf-ſtalks. Specimens from Profeſſor Thunberg, under the name of *S. Virgaurea*, agree with our *cambrica*, which confirms an obſervation made by Mr. Afzelius, that Linneus (in hort. cliff.) had placed this as a variety of the common *S. virgaurea*, whereas it is the plant of the Flora Suecica, and really diſtinct from that of the Hortus Cliffortianus, which is our more common ſpecies.

Dillenius, who regarded it as a ſpecies, diſtinguiſhes it, by its low ſtature, ſlender ſtem, ſmaller, narrower and more hairy leaves, but principally by the inflorescence; having many flowers on the top of the ſtem only, cloſely collected together into a ſhorter blunt ſpike: it alſo flowers earlier, namely at the beginning of june, in gardens, but later in its natural places of growth. In cultivation, it produces ſeveral ſtems from the ſame root, and longer leaves [a].

Lhwyd, who firſt diſcovered this plant in Wales,

[s] Smith brit. & engl. bot. [t] Woodw. Mſs. [u] Gærtner. [x] Engl. bot. [y] Raii ſyn. [z] Withering. [a] Hort. elth.

Digitized by Google

on the top of the mountain called y Glydder, doubted whether it was any thing more than a variety [b]. Mr. Woodward alſo much doubts its being diſtinct; and ſays it ſeems only to differ in having the flowering heads in a cloſer ſpike, the ſingle heads larger, and the florets of the ray broader. The leaves are more hairy, but this is frequently the caſe with plants which grow dwarfiſh and ſtunted. Specimens gathered on the rocky precipice on the ſummit of Ingleborough to the N. W. afford no marks ſufficient to form a ſpecific difference [c].

It has been found by Hudſon about Llanberys, and by Pennant on Llyn y Cwyn near Snowdon. Mr. Hudſon found it on the mountains of Yorkſhire and Weſtmoreland, and Mr. Gough, near Kendal. Mr. Lightfoot ſaw it on the highlands of Scotland.

Plukenet has figured two dwarf varieties (*t.* 235. *f.* 7, 8.) not above two inches high; which ſeem to be only ſtunted plants of the common ſort, owing to their growth in a very barren ſoil. Such Dillenius ſeems to have found near Petersfield in Hampſhire [d], flowering in auguſt.

ζ. Withering's S. lapponica is about ſix inches high, and the ſpike contains about ten flowers. Mr. Afzelius informed Dr. Withering that this Lapland plant had been found in Scotland; and the Dr. had a ſpecimen which he believed came from the mountains of Weſtmoreland. The root-leaves are ovate, on bordered leaf-ſtalks; the ſtem-leaves ſpear-ſhaped and ſeſſile; the flowers in a ſpike-like terminating bunch and in the boſom of the upper leaves: the ſtem is ſtraight and unbranched, as in *cambrica* [e]. Lightfoot's dwarf plant is probably the ſame with this.

27. Native of Labrador. Introduced in 1776, by the Hudſon's-bay company. It flowers in july [f].

28. Linneus ſays it is too nearly allied to the *S. Virgaurea*; and Haller that the *cambrica* ſeems to differ from it in having hoary leaves. It is lower, according to him, than the common Golden-rod, often a long ſpan in height, with fewer, larger flowers, on one-flowered petioles, in a very ſhort ſpike: but theſe marks do not ſeem to be ſufficient to diſtinguiſh it, ſince they agree ſo entirely in the habit. It is frequent in all the Alps [g]; and Pyrenees. Introduced in 1772, by Monſ. Richard. It flowers in july [h].

Mr. Miller ſeems to have ſuppoſed it to be the ſame with the *cambrica*, from which it differs in having a hairy ſtem, the leaves lanceolate acute and ſmooth, and one ſimple upright terminating raceme. In the ſeventh edition of his Dictionary, it is the eighth ſpecies, and is deſcribed as having] the ſtalk about four or five inches high; the leaves ſmall, ſpear-ſhaped, and indented on their edges; the flowers produced ſingly upon long ſlender foot-ſtalks from the axils; they are large, pale yellow, and appear in june.

29. Stalks round, hairy, and near three feet high. Leaves oppoſite, upon ſhort foot-ſtalks, three inches long, and an inch and a quarter broad, their ſurface very rough, of a dark green on the upper ſide, but paler on the under, crenated on the edges. Flowers in ſhort bunches from the upper axils, deep yellow, and pretty large.

30. Stalk ſhrubby, ſeven or eight feet high, dividing into many ſpreading branches, which are ſlender, woody, and covered with a ſmooth gray bark. Leaves two inches and a half long, and an inch broad, of a light green, and upon ſhort foot-ſtalks. Flowers in a looſe terminating corymbus, large, of a pale yellow colour, upon pretty long peduncles. The common calyx is cut almoſt to the bottom. Petiver ſeems to have this plant, under the name of Pulmonaria jamaicenſis, ſalicis folio, calycibus paleaceis. Theſe are both natives of La Vera Cruz in New Spain, where they were diſcovered by Dr. Houſtoun: and conſequently muſt have been cultivated by Mr. Miller before 1733, in which year Dr. Houſtoun died.

[Forſter has one ſpecies (S. arboreſcens) native of New Zealand; and Loureiro two ſpecies (decurrens and cantonienſis) natives of China near Canton.]

PROPAGATION AND CULTURE.

Theſe plants are all hardy, (except the two ſorts laſt mentioned) and therefore will thrive in the open air in England. Many of them having ſpecious panicles of flowers, are great ornaments to the Engliſh gardens at the end of the ſummer, when there is a ſcarcity of other flowers, which renders them more valuable. The European ſorts are ſeldom admitted into gardens, as they do not make any great appearance, but the ſorts from North America are better eſteemed; theſe have been greatly increaſed in their number of late years, and if we can judge from the ſorts which have been introduced from North America within a few years paſt, we muſt ſuppoſe that country abounds with many more ſorts than are yet known.

Theſe plants when they are once obtained, may be propagated in plenty by parting their roots; the beſt time for doing it is in autumn, as ſoon as their flowers are paſt; but thoſe ſorts which do not flower till very late in the year, ſhould be tranſplanted early in the ſpring before they begin to ſhoot, and the roots may be then parted; but if the ſpring ſhould prove dry, they will require water to eſtabliſh them well in the ground, otherwiſe they will not flower ſtrong the ſucceeding autumn. Some of the ſorts ſpread their roots, and propagate much faſter than others, theſe may be tranſplanted and parted every other year; or if the plants are wanted, they may be every year divided, but then they will not flower ſo ſtrong as thoſe which are ſuffered to remain longer unremoved; and thoſe ſorts whoſe roots do not multiply ſo faſt, ſhould be parted only once in three years, if they are expected to flower ſtrong.

The ſorts which grow tall, are not very proper furniture for ſmall gardens, becauſe they require much room, for theſe ſhould be allowed four or five feet, otherwiſe their roots will intermix with thoſe of the neighbouring plants, and draw away their nouriſhment; therefore theſe plants are proper ornaments for large extended walks round fields, or for the borders of wood-walks, where they will make a fine appearance during their ſeaſon of flowering; and as they require little culture, they are adapted to thoſe places. They will thrive in almoſt any ſoil, but when they are planted in good ground they will grow much larger, and make a better appearance.

Theſe plants may alſo be propagated by ſeeds, but it is only the early flowering kinds which perfect their ſeeds in England. Theſe ſeeds ſhould be ſown in autumn ſoon after they are ripe, for thoſe which are kept out of the ground till ſpring ſeldom ſucceed, or at beſt do not come up the ſame year; they may be ſown in drills upon a bed of freſh earth, at about a foot aſunder, but the ſeeds ſhould be ſcattered pretty thick in the drills, and covered lightly over with fine earth. When the plants come up, they muſt be kept clean from weeds, and where they are too cloſe, part of them may be drawn out, and planted in a ſhady border, to allow room for the others to grow till autumn, when they ſhould be tranſplanted where they are deſigned to remain. The following year they will flower, and their roots will abide many years.

The two laſt mentioned ſorts being natives of a warm country, will not thrive here, unleſs they have artificial heat in winter, eſpecially the laſt ſort, which requires a warmer ſituation than the other. Theſe plants ſhould be planted in pots, and the laſt ſhould be plunged into the tan-bed in the ſtove, and treated in the ſame way as other tender plants from the ſame country. This may be propagated by cuttings, which, if planted in pots filled with loamy earth, and plunged into a moderate hot-bed, will take root. The other ſort is propagated by parting the roots, in the ſame manner as the ſorts before mentioned; theſe ſhould be kept in a moderate ſtove in winter, and in ſummer may be placed abroad in a ſheltered ſituation.

11. Sonchus pinnatus. *Wing-leaved Sow-thiſtle.*
Ait. kew. 3. 116.
Peduncles naked, calyxes even, leaves pinnate, pinnas linear-lanceolate ſomewhat toothed.

12. Sonchus radicatus. *Long-rooted Sow-thiſtle.*
Ait. kew. 3. 116.
Peduncles naked together with the calyxes ſmooth, ſtem almoſt naked, root-leaves lyrate even on both ſides, lobes triangular ovate.

13. Sonchus floridanus. *Small-flowered Sow-thiſtle.*
Lin. ſpec. 1118. *ſyſt.* 712. *Reich.* 3. 623. *Lour. cochinch.* 480. *ed. Willd.* 586. *Gron. virg.* 115.
S. annuus canadenſis altiſſimus laciniatus, flore cæruleſcente. *Vaill. act.* 1721. *p.* 198.
Lactuca altiſſima, folio ſonchi laciniato, flore parvo cæruleo. *Boerh. lugdb.* 1. 81.
Peduncles ſcaly, leaves lyrate-baſtate.

14. Sonchus ſibiricus. *Willow-leaved Sow-thiſtle.*
Lin. ſpec. 1118. *Reich.* 3. 623. *fl. ſuec. n.* 690. *Gort. ingr.* 119. *Lour. cochinch.* 481. *ed. Willd.* 586. *Kniph. cent.* 10. *n.* 82.
Peduncles ſcaly, leaves lanceolate undivided ſeſſile.

15. Sonchus tataricus. *Tartarian Sow-thiſtle.*
Lin. ſyſt. 712. *Reich.* 3. 623. *mant.* 572. *Gmel. ſib.* 2. 11. *t.* 3.
Peduncles naked, leaves lanceolate toothed runcinate.

16. Sonchus tuberoſus. *Tuberous-rooted Sow-thiſtle.*
Lin. ſyſt. 712. *ed.* 13. 346. *Reich.* 3. 624.
Lower leaves runcinate, upper ſagittate.

---

17. Sonchus quercifolius. *Oak-leaved Sow-thiſtle.*
Desfont. atlant. 225. *t.* 213.
Stem ſhrubby, leaves wedge-form, lobed at the edge, lobes remote acute toothed, the end ones in threes.

18. Sonchus anguſtifolius. *Narrow-leaved Sow-thiſtle.*
Desfont. atlant. 225.
Leaves glaucous ſmooth linear, pinnules diſtant toothletted.

19. Sonchus chondrilloides.
Desfont. atlant. 226.
Chondrilla ſicula tragopogonoides maritima. *Bocc. ſic.* 13. *t.* 7. *f.* A.
Root-leaves unequally pinnatifid toothed narrow, branches rod-like ruſhy one-flowered.

DESCRIPTIONS, *&c.*

1. Stem ſmooth, decumbent, ſometimes erect, ſimple or ſparingly branched. Leaves ſmooth, glaucous, acute. Flowers few, panicle-corymbed: peduncles ſmooth or tomentoſe. Calyx ſmooth, or tomentoſe at the baſe. Flower the ſize of the common ſort. Seed-down white, villoſe.—It is diſtinguiſhed by its lanceolate, glaucous, toothletted leaves. Sometimes the ſtem has only one or two flowers [i].

The ſtem, according to Cavanilles, is round and near two feet high: the leaves near a foot long, narrow, ſomewhat earletted: the flowers terminating, two or three, on ſhort pedicels: ſcales of the calyx lanceolate, the outer ones ſhorter: corollets yellow, with a villoſe tube. He remarks, that Plukenet's figure, referred to by Linneus differs very widely from this plant.

Native of the South of Europe, and of Barbary, in ſandy wet places. Introduced in 1774, by Monſ. Richard. It flowers from july to ſeptember [k].

[i] Desfontaines. [k] Hort. kew.

2. Root perennial, fleſhy, branched in tufts. Stems upright, three feet high, ſimple, leafy. Leaves alternate, embracing, runcinate-lyrate, toothletted, even, glaucous beneath; the lobes acute, that at the end very large and deltoid: the upper ones linear and ciliate. Raceme terminating, ſolitary, upright, hiſpid with red ſtretched-out glandular-viſcid hairs. Bractes linear. Calyx hiſpid, red. Corolla blue-purple, twice as long as the calyx. Anthers red. Seeds compreſſed. Seed-down rugged, not feathered [l].

Native of Canada and the European alps. Found on the borders of corn fields about Willington and Howden-Pans in Northumberland [m].

This has been confounded with the *alpinus* of Linneus, from which it differs widely. The trivial name *canadenſis* being improper for a plant common on the alps of Europe, Dr. Smith has judiciouſly reſtored that by which it is known in old authors.

3. Mr. Curtis has well diſtinguiſhed this ſpecies from the *arvenſis*, in oppoſition to the opinion of Haller. The root is perennial, fleſhy and branched, but not creeping; the whole herb is twice or thrice as large, though the flowers are rather ſmaller, and generally a little paler; the ſtem-leaves are longer, and their baſe is arrow-ſhaped, terminating in a pair of long narrow divaricating lobes, inſtead of being heart-ſhaped, their margin is minutely toothed; the panicle aſſumes nearly the ſhape of an umbel or cyme, varying in the number of flowers; the ſtalks as well as the calyx are rough with denſe ſhort black glandular hairs or briſtles, in which reſpect, as well as in the ſeeds and their down, it much agrees with *S. arvenſis* [n].

Johnſon (in Ger. emac.) and Sam. Dale (in Ray hiſt.) remarked the greater ſize of this ſpecies, with ſmaller flowers, which induced Ray to conſider them as diſtinct, contrary to the opinion of the Bauhins.

The root, when old, forms a large ſtool, and throws out numerous ſtems from four to ſeven feet in height; the plant from which Mr. Sowerby's drawing is made was ſeven feet high; Dr. Smith ſays, from ſix to eight, Mr. Curtis ſix feet or more, but that he has ſeen it ten feet high; he conſiders it as the talleſt of our Engliſh herbaceous plants; and remarks that it flowers later by three weeks than the *arvenſis*.—Lower ſtem-leaves very large, upper ſmaller, embracing, and arrow-ſhaped at the baſe, pinnatifid with two or three pairs of lanceolate pinnas, and a very long terminating one, ſmooth, finely toothed at the margins: the pinnas are variouſly bent, and the main nerve does not run through the middle, but near the interior edge: uppermoſt leaves arrow-ſhaped at the baſe, lanceolate upwards and acuminate. Bractes awl-ſhaped. Calyx of numerous ſtrap-ſhaped unequal ſcales, hairy, but the hairs not ſo long as in *arvenſis*, though as in that terminated by globules [o].

Native of Germany, Flanders, France, Italy, Hungary, Denmark and England. Thomas Williſel found it on the banks of the Thames not far from Greenwich. Mr. Curtis ſays it occurs ſparingly in the marſhes about Blackwall and Poplar. Mr. Sowerby's ſpecimen was gathered between Greenwich and Woolwich, late in july. Near Stretham-ferry in the iſle of Ely, it has not been found for many years. Mr. Ray mentions his having gathered it in Suſſex, and near Frankfort on the Mayne, where Cluſius alſo found it.

4. Root perennial, creeping, milky, compoſed of oblong fleſhy branches, which render it very difficult to be extirpated. Stem three or four feet high, upright, little branched, roundiſh or ſlightly angular, hollow, leafy, rough with glandular briſtly hairs. Leaves alternate, runcinate, ſharpiſh, ſmooth, ſhining, fringed with little ſpinous teeth, paler on the under ſide; the upper leaves heart-ſhaped at the baſe and embracing; the uppermoſt entire. The larger leaves are notched with triangular teeth, which are again much ſharper toothed, the teeth more ſpinous than in the *paluſtris*: the upper ones are lanceolate, but not ſo much acuminated as in that. Panicle ſomewhat cymoſe or umbellate, terminating, few-flowered.

[l] Smith brit. [m] Wallis, 186. [n] Engl. bot. [o] Woodw. Mſs.

Digitized by Google

Calyx and peduncles, as well as the upper part of the ſtem, clothed with ſpreading brown glandular briſtles. Withering ſays they are pale green (or yellowiſh,) and are terminated by yellow globules: this is in their young ſtate. Dr. Abbot remarks, that after flowering they are turgid at the baſe: and Mr. Woodward, that theſe hairs are more numerous and longer than in *paluſtris*. Calyx-leaves more pointed than in *paluſtris*. Flowers very large and conſpicuous, of a bright gold-colour, externally reddiſh; on longer peduncles than thoſe of *paluſtris*. Each floret has a hairy tube. Seeds ovate, compreſſed, bay-coloured, both longitudinally and tranſverſely grooved. Seed-down ſmooth [p].

Mr. Curtis remarks, that this ſpecies is properly termed *arvenſis*, being commonly found in corn fields, where its large yellow flowers towering above the corn render it a very conſpicuous plant in july and auguſt. Its ſize, creeping root, and numerous globular hairs on the calyxes and peduncles, ſufficiently diſtinguiſh this from *S. oleraceus*. Many of the ſeeds prove abortive; owing probably to its creeping ſo much at the root. Cows and goats are ſaid to eat this plant, and horſes to be very fond of it. The leaves, like thoſe of the common Sow-thiſtle, applied outwardly by way of cataplaſm, have been found ſerviceable in inflammatory ſwellings.

5. Native of Jamaica. Sloane conſidered it as our common ſmooth Sow-thiſtle.

6. Root annual, fuſiform, whitiſh, milky. Stem from one to three feet high, upright, branched, eſpecially towards the top, round except near the top where it is ſomewhat angular, ſmooth, tender, brittle, hollow, leafy, ſometimes purpliſh. Leaves embracing, ſmooth, glaucous, runcinate or pinnatifid, with the lobes acute, and more or leſs toothed or ſpiny. Peduncles axillary and terminating, forming a ſort of cyme, downy with a white and very ſoft lanugo, which quickly falls off. Calyx before flowering cylindrical and truncate, afterwards bellying out and forming a cone; ſcales ſmooth and pointed. Corolla pale yellow. Seed oblong, flattened, angular, grooved, ſomewhat rugged, notchletted. Seed-down very fine and ſmooth. Receptacle rugged with little prominent points, and ſhining [q].

Gærtner deſcribes the receptacle before it is fully ripe as concave, and having very minute depreſſed papillæ ſcattered over it: the ſeeds obovate, compreſſed, having three or five longitudinal ſtreaks, and other tranſverſe ones more indiſtinct and ſlender; the colour is ruſty yellow or cinnamon. Seed-down ſnow-white, three times as long as the ſeed.

The common Sow-thiſtle is ſubject to vary extremely: among the varieties Haller and others make the *aſper* or prickly one a diſtinct ſpecies; and the old botaniſts formed ſeveral others, from the ſize, breadth and diviſion of the leaves, &c. but theſe variations are owing merely to ſoil and ſituation; even the prickly one may readily be traced into the ſmooth, in a garden overrun with theſe plants.

The Sow-thiſtle ſeems to have nearly the ſame properties as Dandelion and Succory, but it is little regarded as a medicine. It is a favourite food with hares and rabbets; and is ſaid to be eaten by goats, ſheep and ſwine, but not to be reliſhed by horſes. The young tender leaves are in ſome countries boiled and eaten as greens: and it is even affirmed that the tender ſhoots of the ſmooth variety, boiled in the manner of Spinach, are ſuperior to any greens not in common uſe.

Common Sow-thiſtle abounds moſt in gardens, and is often met with on walls. It is more injurious to the ſlovenly gardener than the huſbandman: and flowers chiefly in july, auguſt, and ſeptember [r].

7. Root annual. Stem very much branched, with ſcattered, glutinous hairs on it. Pedicels clothed with a white nap. Calyxes cylindrical, with ſpreading hairs ſcattered over them. Leaves ſmooth, tender, pinnatifid, unarmed [s].

It is thus deſcribed more at large by Monſ. Desfontaines. Stems procumbent, ſmooth, ſtriated, brittle, hollow. Leaves ſmooth, very tender, deeply pinnatifid; pinnules remote, unequal, lanceolate, often irregular, toothed, acute, ſublanceolate, increaſing from the baſe of the petiole to the top, often bowed and turned back; the lobe of the baſe much the largeſt, and embracing; the end one ſometimes ſubhaſtate. Flowers corymbed. Peduncles leafleſs. Calyx ovate, clothed at the baſe with a white nap; leaflets linear, hairy. Flowers yellow, nearly as big as in *S. arvenſis*. Seed-down whitiſh, villoſe, ſimple, ſeſſile. Seed ſmall, browniſh, even, oblong, ſmooth.

This plant varies much. The ſtems have rufous glutinous hairs thinly ſcattered over them, or are frequently quite ſmooth. The leaves are ſometimes pinnate, ſometimes pinnatifid; the ſegments in ſome plants are wide, in others almoſt linear; and in ſome the uppermoſt leaves are entire and lanceolate. The very tender pinnatifid leaflets, and the calyx tomentoſe at the baſe, diſtinguiſh it from the other ſpecies.

Native of Italy and the South of France. Found alſo in Barbary, both in corn fields and on the ſea ſhore, by Monſ. Desfontaines. Dr. Smith obſerved it on the walls of Rome; and remarks, that it flowers perpetually, and is eaten by the common people as a ſalad [t]. It was cultivated in the Chelſea garden in 1713 [u].

8. This very much reſembles the next ſpecies, but the corolla has only one row of florets, or are fewer by half than in that, but four times as big. Stem the height of a man. Leaves two feet long, runcinate like thoſe of Dandelion, even above, rugged on the veins beneath. Stem-leaves narrower and ſharper. Panicle terminating, with naked peduncles. Corolla like that of Succory. The calyx exſudes very ſmall, ſcattered reſinous globules. Seed-down ſtiped, as in *Lactuca* [x].

Gouan ſays that this is very different from *S. alpinus* in the whole of its habit. The root is perennial, woody and branched, whereas in that it is annual. Stem green, very ſmooth, very finely ſtreaked. Root-leaves and lower ſtem-leaves runcinate, and like thoſe of *Eryſimum Irio*, &c. The other ſtem-leaves reſemble theſe, but have narrower pinnules, more torn, a wider baſe, and commonly more ſharply toothletted: the uppermoſt very ſmall, with a wide ſheath terminated by a very long entire awl-ſhaped leaflet. Pedicels naked for the moſt part, but never covered with ſcattered ſtrap-ſhaped bractes; and the leaves from whoſe axils the peduncles ſpring are wider, haſtate-cordate at the baſe, not awl-ſhaped as in *S. alpinus*. Calyxes twice as large and very ſmooth; the ſcales larger, and the outer ones at the baſe cordate, as in *Scorz. picroides*. Corollas blue.—Native of the Pyrenees.

9. Root annual. Stem ſimple, upright, round, ſtriated, glaucous, the height of a man and upwards. Leaves alternate, irregularly toothed, ſmooth, glaucous beneath, with the terminating ſegment ſcarcely larger than the reſt. Raceme compound, leafy, very long, terminating, upright, many-flowered; flowers upright. Peduncles branched, wholly covered with alternate triangular acute ſmooth bractes. Calyx oblong, bellying at the baſe, ſmooth; ſcales lanceolate, acute, green, pale at the edge. Corolla blue. Seeds contracted, ſtriated. Seed-down ſimple, ſeſſile, appearing rugged when viewed with a magnifying glaſs.

This has been much confounded with the ſecond ſpecies, from which it is totally different, as appears clearly from comparing the ſpecific differences. Dr. Smith has not ſeen a ſpecimen of it in any herbarium except in his own, and Leche's now in the poſſeſſion of Sir Joſeph Banks. Linneus found it very common on the ſide of the Lapland alps in 1732 [y].

The natives eat the ſtalks raw, like Angelica, ſtripping off the bark; but Linneus found them too bitter for his palate [z].

I have given the ſynonyms from the Flora Lapponica, but probably they do not belong to this ſpecies.

10. Stem ſhrubby, ſmooth, milky, upright, ſcarcely branched, round, thick, gray. Branches alternate, ſpreading. Leaves ſeſſile, cluſtered, ſinuate-runcinate or repand-ſinuate, unequally toothed, acute, very ſmooth, bright green on both ſides, ſpreading, flat, milky, a foot long and three inches wide. Corymbs terminating, very looſe, upright, few-flowered. Peduncles alternate, ſpreading, many-flowered, ſomewhat mealy. Pedicels one-flowered, ſcaly with little ſcattered linear acute recurved bractes, ſwelling at the top and hollow. Flowers yellow, two inches wide. Bractes like involucres, lanceolate, acute, waved, ſeſſile, the upper ones gradually ſmaller. Calyx pitcher-ſhaped: ſcales lanceolate, acute, reflex, gibbous at the baſe, the upper ones gradually larger. Seeds oblong, ſtriated, browniſh. Seed-down ſilky, white. Receptacle flat, honey-combed [a].

Native of Madeira, where it was found by Mr. Francis Maſſon, and introduced by him in 1777. It flowers from april to july [b].

11. Native of Madeira. Introduced in 1777.

12. Native of the Canary iſlands. Introduced in 1780. It flowers in july. Both theſe are ſhrubby, and were found by Maſſon [c].

13. Stem annual, four feet high, upright, round, ſmooth, branched. Leaves ſeſſile. Flowers yellow, terminating, many [d].

Native of North America; and of China near Canton, according to Loureiro.—Cultivated here in 1713; flowering in july, and biennial [e].

14. Stem ſuffruticoſe, four feet high, ſimple, upright, round. Leaves ſomewhat toothletted, ſmooth. Flowers yellow, in a large ſpreading panicle. Calyx oblong, ventricoſe, ſmooth [f]. Seed-down ſimple ſeſſile. This as well as the *alpinus* varies with a white flower [g].

Native of Sweden and Ruſſia,—according to Loureiro, of China alſo near Canton. Cultivated by Mr. Miller in 1759. It flowers in july and auguſt, and is perennial [h].

15. Root perennial, creeping. Plant very like the preceding. Stems even, twice as high as in that. Moſt of the leaves lanceolate, pinnatifid-toothed or ſubruncinate, even, with a white rib; ſtature of *S. arvenſis*. Flowers blue, altogether like thoſe of *S. ſibiricus* [i].

Native of Siberia. Introduced in 1784, by William Pitcairn, M. D. [k]

16. This reſembles the *tataricus*, but the root is not at all creeping. Corollas erect, blue. All the piſtils in the centre of the flower.—Native place unknown [l].

17. Stems ſhrubby, branched, fleſhy, roughened with the rudiments of the petioles, as thick as the finger or even the thumb. Leaves ſcattered, glaucous, very ſmooth, ſomewhat fleſhy, perennial, running down along the petiole; the teeth of the lobes ſnow-white at the top. Petioles cluſtered, flat above, embracing. Flowering branches terminating, dichotomous, ſtriated, ſmooth. At the baſe of each peduncle a leafy ſcale. Flowers in a looſe corymb. Peduncles unequal, with a few ſcales on them, one-flowered. Calyx cylindrical, looſely imbricate, ſmooth: outer ſcales wide, ovate, leafy, whitiſh and ſhrivelling at the top. Flowers yellow: floſcules twice as long as the calyx. Seeds oblong, ſmooth: ſeed-down ſeſſile, ſimple, ſnow-white, villoſe. It is a very handſome ſingular ſpecies, and quite diſtinct.—Native of the mountains of Caſsa in Barbary.

18. Root long, fuſiform, the thickneſs of a gooſe quill or the little finger, putting forth fibres all over. Stem none or ſhort. Leaves ſomewhat fleſhy, pinnate: pinnules remote, unequal, toothed; teeth ſhrivelled and whitiſh. Peduncles one or many-flowered, having few ſcales ſcattered over them, and ſhorter than the leaves. Calyx ſmooth, ovate; the outer ſcales ovoid, the inner ovate-lanceolate, frequently having a whitiſh membranaceous point. Corolla yellow, the ſize of *S. arvenſis*.—Found near Caſsa by Desfontaines.

19. Plant glaucous and very ſmooth. Segments of the root-leaves ſomewhat remote, acute or obtuſe, whitiſh at the tip; ſtem-leaves few, narrow-lanceolate, with acute remote teeth. Branches upright, ſlender, unequal, clothed with ſmall, linear or ſcaly leaves. Calyx like that of *Lactuca*, ſmooth, cylindrical, imbricate with widiſh lanceolate ſcales, hoary at the tip. Floſcules yellow, twice as long as the calyx. Seed-down ſimple, white, villoſe, ſeſſile. Seed ſmall, oblong, brown. It has the appearance of *Hieracium porrifolium*. Boccone's figure repreſents the ſegments of the leaves too ſharp, and the peduncles too ſhort; the flowers are alſo ill drawn: but it is certain that it is the ſame with this, from the ſpecimen in his herbarium at Paris.

Native of ſandy fields about ancient Carthage [m].]

PROPAGATION AND CULTURE.

Many of theſe are weeds and therefore not to be planted in gardens, but extirpated continually, not only in the garden itſelf, but in all the parts near it; their winged ſeeds being wafted to a conſiderable diſtance.

[The foreign ſorts may be propagated by ſeeds; and thoſe which are ſhrubby, by cuttings alſo.

DESCRIPTION, *&c.*

This is a tree. The leaves are oppoſite, ſubſeſſile, oblong, quite entire, like thoſe of *Hypericum*. Flowers terminating, ſolitary, large. Petals red. Fruit reſembling that of *Meſembryanthemum*, with an acid bladdery juice [n].

Native of the Molucca iſlands, and the bogs of New Guinea; alſo of Cochinchina, on the banks of rivers.

[a] L'Heritier. [b] Hort. kew. [c] Idem. [d] Loureiro. [e] Hort. kew. [f] Loureiro. [g] Linn. ſpec. [h] Hort. kew. [i] Linn. mant. [k] Hort. kew. [l] Linn. ſyſt. [m] Desfontaines. [n] Linn. ſuppl.

Loureiro

Loureiro obſerved it on the eaſt coaſt of Africa, of a lower ſtature, with ſome of the leaves emarginate, but agreeing with the other in the flower and fruit.

Gærtner deſcribes the berry as ſuperior, globular, flatted a little, terminated by the filiform ſtyle, very ſmooth, glaucous, many-celled: rind very thin, membranaceous, adhering cloſe to the pulp, which is hardiſh, granular and whitiſh: cells twelve or more, filled with the pulp and ſeeds intermingled: partitions thin, not ſeparate from the pulp. Seeds very numerous, of different ſhapes, having the appearance of fragments of broken teeth, but for the moſt part irregularly club-ſhaped, curved, and reſembling ivory; they lie in the pulp like pebbles in a pavement.

Another ſpecies is figured in Major Symes's account of an Embaſſy to the kingdom of Ava, under the name of *Sonneratia apetala*. It is thus deſcribed in that ſplendid work, p. 477. The apetalous Sonneratia is a moſt beautiful tree, reſembling the weeping Willow, but loftier: the branches are ſcattered, pendulous, round, and ſmooth; the ſmaller branches or twigs oppoſite, divaricating, ſubbrachiate, ſmooth, filiform. Leaves on the twigs few, oppoſite, ovate-lanceolate, one of the margins more gibbous than the other, quite entire, commonly blunt, without nerves or veins, flat, ſomewhat fleſhy. Petiole linear, depreſſed, ſharp at the edge on each ſide, ſhort, oblique, ſmooth. Flowers drooping, greeniſh, ſmooth, the ſize of a nutmeg, axillary, ſubſolitary; the terminating ones moſtly in threes. Peduncles ſhorter by half than the leaves, pendulous, one-flowered, ſmooth, whitiſh, thickened towards the top, jointed, angular. Calyx coriaceous, thick, four-cleft beyond the middle; ſegments patulous, acute. Corolla none. Nectary a thick membrane, faſtened to the bottom of the calyx, with the margin entire, ſtaminiferous, produced beyond the diviſion of the calyx. Filaments erect at the baſe, but curved in above, the length of the calyx, placed in ſeveral rows on the top of the nectary. Anthers ſmall, upright, cordate. Germ turbinate. Style round, longer than the ſtamens, flexuoſe. Stigma very large, concavo-convex, reſembling a cap. Fruit an orbicular depreſſed Pome, girt at the baſe with the ſpreading calyx, eight-celled, pointed with the permanent ſtyle. Seeds very many, angular, neſtling in the pulp.

Native of Rangoon in the kingdom of Ava, on wet inundated banks by the coaſt. Called in the Birman language *Kam-ba-la*.

It is clearly diſtinguiſhed from that of the Moluccas and Cochinchina, by having the calyx divided into four parts only, and in the want of a corolla. In theſe circumſtances it recedes from the generic character. Various are the names of the fruit: in Syſtema Vegetabilium it is a capſule, in Aublet, Sonnerat, Juſſieu and Gærtner a berry, in Loureiro a drupe, in Symes a pome; it ſeems to have the beſt claim to the name of a berry.

SOPEBERRY. See *Sapindus*.

Lin. gen. n. 508. *Reich. n.* 551. *Schreb. n.* 694. *Gærtn. t.* 149. *Juſſ.* 352.

Claſſ. 10. 1. Decandria Monogynia.

Nat. order of *Papilionaceæ* or *Leguminoſæ*.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, ſhort, bell-ſhaped, gibbous at the baſe above: *mouth* five-toothed, oblique, obtuſe.

COR. Papilionaceous, five-petalled. *Standard* oblong, gradually wider, ſtraight, reflexed at the ſides. *Wings* two, oblong, appendicled at the baſe, length of the ſtandard. *Keel* two-petalled, with the petals conformable to the wings, the lower margins approximating and boat-ſhaped.

STAM. *Filaments* ten, diſtinct, parallel, awl-ſhaped, length of the corolla within the keel. *Anthers* very ſmall, riſing.

PIST. *Germ* oblong, cylindrical. *Style* ſize and ſituation of the ſtamens. *Stigma* obtuſe.

PER. *Legume* very long, ſlender, one-celled, knobbed at the ſeeds.

SEEDS very many, roundiſh.

OBS. *It agrees in every thing with the plants of the claſs* Diadelphia, *except in having all the filaments ſeparate.*

ESSENTIAL CHARACTER.

Cal. five-toothed, gibbous above. *Cor.* papilionaceous, with the wings of the ſame length with the ſtandard. *Legume.*

Thund. prodr. 79.
Leaves ſimple ovate hirſute.

DESCRIPTIONS, &c.

1. This magnificent tree is a native of New Zealand; where it was found by Sir Joſeph Banks, and introduced in 1772. It diſplays its pendulous branches of large golden flowers in may and june [o].

2. This is a ſmooth tree, with ſmall leaves almoſt wedge-ſhaped. Flowers large and yellow. Legume compreſſed, toruloſe, flat at the back and belly, keeled at the ſides with longitudinal membranes, as in *Lotus tetragonolobus* [p].

Native of New Zealand, where it was found by Sir Joſeph Banks, and introduced in 1772. It flowers in may and june [q].

3. This reſembles the next ſpecies, but is ſmooth all over. Leaves unequally pinnate, with the leaflets in ſix pairs, ovate-lanceolate, bluntiſh. Calyx indiſtinctly five-toothed [r].

Native of Siberia. Introduced in 1785 by Mr. John Bell [s].]

4. Root perennial, creeping, from which ariſe ſeveral erect ſtalks from three to four feet high. Leaves unequally pinnate. Flowers pale blue and ſmall, in long axillary ſpikes ſtanding erect cloſe to the ſtalk.

[Stems ſtriated, the thickneſs of a reed. Leaves from top to bottom: pairs of leaflets ten or more, deep green above, whitiſh and ſilky beneath, hairy not only there but along the edges and above, though leſs ſo. The ſtem puts forth a few branches only towards the top: theſe have leaves like thoſe of the ſtem, but much ſmaller and more hairy. Spike terminating, long, compoſed of many flowers, neither looſely nor very cloſely put together, of a whitiſh herbaceous or pale yellowiſh colour: calyx divided into five blunt ſhort ſegments, and of the ſame colour with the corolla. The flowers riſe obliquely or incline gently, but are not pendulous. Germ ſlender, ſilky. Legume an inch and half or two inches long. The flowers ſmell ſweet [t].

Native of the Levant. Cultivated in 1732, by James Sherard, M. D. It flowers in july and auguſt [u].]

5. Stem downy, ſix or ſeven feet high. Leaves unequally pinnate, compoſed of five or ſix pairs of leaflets. Flowers in ſhort looſe axillary ſpikes, large and yellow, not unlike thoſe of Spaniſh Broom, void of ſcent. Pods larger, woolly, five or ſix inches long, having four or five large ſwellings, in each of which is a roundiſh brown ſeed as big as a pea.

[o] Hort. kew. [p] Linn. ſuppl. [q] Hort. kew. [r] Willdenow. [s] Hort. kew. [t] Dillenius. [u] Hort. kew.

Digitized by Google

[Gærtner deſcribes the legume or pod as pedicelled, necklace-form, ſilky-tomentoſe, white, many-celled; the cells divided by ſpongy iſthmuſes: the valve ſcarcely open. Seeds ſeparate, four or a few more in the whole, ſubglobular, attenuated at each end into a ſhort point, and having an oblong excavation at the navel, ſmooth, of a cheſtnut-bay or pale red colour.

The whole plant is clothed with a thick white nap. Leaflets about ſeventeen, ovate and blunt, or roundiſh. Calyxes tomentoſe. The plant is ſometimes entirely ſmooth [x].

Native of Ceylon; and according to Forſter, of the Society Iſles. Mr. Miller ſays, of Senegal in Africa, and of the Weſt Indies, particularly Jamaica, where it is called Sea-ſide Pigeon-Pea; but he probably confounded this with the next ſpecies, from which it does not materially differ, in Linneus's opinion.

6. This is a ſhrub, with a round hoary-pubeſcent ſtem, and round ſpreading ſubtomentoſe branches. Leaves on alternate, long, ſpreading, round, hoary petioles, thickened at the baſe: leaflets oppoſite, moſtly ſix paired with an odd one, entire, flat, hoary, white-tomentoſe beneath, on ſhort round petioles. Flowers in a ſort of ſpike. Peduncle terminating, erect, a foot long, ſimple, round, many-flowered: flowers cloſe, biggiſh, peduncled, yellow. Calyx bluntly five-toothed, with the three lower teeth longer, hoary, pale green. Germ hoary. Legume pedicelled, very long, at firſt filiform, then ſwelling out and jointed. Seeds roundiſh [y].

The leaves are leſs tomentoſe than in the preceding, according to Linneus, who ſuſpects it to be only a variety of that.

Native of the Weſt Indies. In Jamaica, according to Browne, this ſhrubby plant grows chiefly in the low lands, near the ſea, and riſes generally to the height of ſix or ſeven feet.—Cultivated in 1739, by Mr. Miller [z]. In Jamaica it flowers in may and june.

7. This is a ſmall tree, ten feet high, with a whitiſh bark, and a hard wood: branches ferruginous tomentoſe. Leaflets ſmooth on both ſides and rigid. Panicles terminating, branched. Corolla large, blue, ſmelling ſweet. Legume ovate, villoſe, woody; in which there is only one large ſpherical ſcarlet ſeed with a black ſpot.

Native of Jamaica and other iſlands of the Weſt Indies [a]. Browne ſays he has ſeen this tree often in Montſerrat; that it riſes by a moderate trunk, and ſpreads much towards the top; that the ſeeds are pretty large, and well marked with a proportioned large ſpot. He names it the Red-Bead Tree.

8. Branches round, even, purpliſh. Leaves alternate, unequally pinnate: leaflets ſuboppoſite, on very ſhort petioles, oblong, blunt with a point, quite entire, glaucous beneath, ſmooth, ſpreading, an inch long. Flowers on panicled racemed branchlets. Legumes ſomewhat fleſhy, ſingle or two-jointed, the joints globular [b].

The leaves are like thoſe of *Robinia Caragana*; they are ſcattered, and the leaflets are ovate, thin, even on both ſides, from ſeven to eleven in number; the lower ones a little ſmaller. Racemes ſmall. Flowers white, of the ſame ſize as in Indigo.

Native of Japan [c]. Introduced in 1753, by Mr. James Gordon [d].

9. The whole plant is ſmooth. Leaves alternate: leaflets ovate-oblong, petioled, commonly ſeven, ſharpiſh, remote from each other. Raceme terminating, long, naked. It is about the ſame-ſized plant with *tomentoſa* [e].—Native of the Eaſt Indies.

Willdenow, following Lamarck, has divided this genus into two, *Sophora* to which the foregoing, and *Podalyria* to which the following ſpecies belong. In the firſt the calyx correſponds with the generic character, and the pod is moniliform or like a necklace of beads: in the ſecond, the calyx is ſubbilabiate, and the pod only ſwelling. The name is given from Podalirius, one of the ſons of Æſculapius.—

——— "Ασκληπιοῦ δυω παιδε,
"Ιητηρ αγαθω, Ποδαλειριος ηδε Μαχαων." *Hom. Il.* 2. 731.

10. This is a tender pubeſcent ſhrub, when more advanced in its wild ſtate naked; having the appearance of *Amorpha*. Leaves alternate, unequally pinnate: leaflets twenty-three, narrow-lanceolate, equal, quite entire, ſhining above, ſubtomentoſe beneath. Raceme terminating, compoſed of white flowers reſembling thoſe of *Crotalaria* and recurved. Filaments interwoven as it were with villoſe hairs. Legume oblong, compreſſed, tomentoſe. Seeds from three to ſix, very hard [f].

Native of the Cape of Good Hope. Introduced in 1773, by Mr. Francis Maſſon [g].

11. This is a ſhrub, the height of a man. The root has the ſmell and taſte of Liquorice. Stem upright, round, tubercled, gray: branches alternate, ſpreading, like the ſtem. Leaves alternate, unequally pinnate, ſpreading, eight inches long: petioles round on one ſide, channelled on the other, pubeſcent. Leaflets from twelve to fifteen pairs, oppoſite, on ſhort petioles, thoſe of the outmoſt longer, quite entire, one-nerved, bright green, paler beneath, ſpreading very much, flat. Stipules linear, acute, pubeſcent, browniſh, erect, permanent. Racemes axillary, ſolitary, peduncled, ſpreading, bracted, pubeſcent, four or five inches long. Flowers alternate, nodding, yellow, eight or nine lines in length, on round pedicels jointed at the top. Bractes lanceolate, acute, concave, preſſed cloſe, one under each pedicel, pubeſcent, brown. Calyx half-four-cleft, pubeſcent; ſegments lanceolate, acute, erect, the upper one twice as wide as the reſt and bifid. Germ pedicelled, linear, compreſſed, villoſe. Legume oblong, attenuated at the baſe, acuminate, compreſſed, having a longitudinal raiſed line at the lower ſuture on each ſide, an inch and half long, and half an inch wide. Seeds few (about three) oblong, ſubreniform [h].

Monſ. L'Heritier united this plant with the Robinias, though he perceived that it receded from them in ſeveral circumſtances. Monſ. Lamarck named it *Virgilia* from the celebrated Roman poet. Willdenow has joined it to his *Podalyrias*.

Native of Africa. Found by James Bruce, Eſq. who gave ſeeds of it to the Paris garden, where it flowers at the end of ſummer or the beginning of autumn, and ſometimes perfects the fruit [i]. It was introduced at Kew in 1777, by Monſ. Thouin, and flowers there in july [k].

12. This ſhrub very much reſembles *Robinia Halodendron*. The legumes are flat and one-ſeeded.

Native of Siberia, on ſandy hills, in the Songarian deſert, by the river Bekun [l].

13. The keel of the corolla is horned on both ſides, as in *Indigofera* [m].—Native of the Cape of Good Hope. Introduced in 1787, by Mr. Francis Maſſon. Shrubby [n].

14. Native of the Cape of Good Hope [o].

15. Stem herbaceous, moſt commonly decumbent. Leaves cuneate-oblong, ſmooth, yellowiſh green. Stipules enſiform, longer than the ſhorteſt petiole [p]. Flowers blue. Legume pedicelled, inflated, ſwelling next the ſuture to which the ſeeds are fixed; on the oppoſite ſide, compreſſed and keeled, papery, dark brown, one-celled. Receptacle fungous, white, ending in various conoid proceſſes, inſtead of umbilical chords, to which the ſeeds are faſtened in ſeveral rows. Seeds numerous, reniform, ſmooth, dun-coloured. By the calyx and fruit this ſpecies has a greater affinity to *Crotalaria* than to *Sophora* [q].

Native of Carolina. Cultivated in 1758, by Mr. Miller. It flowers in june and july [r].]

16. Root perennial, from which ariſe ſeveral ſtalks about a foot and half high, ſending out from the bottom a great number of ſmall branches. The flowers come out towards the end of the branches in ſhort ſpikes; they are yellow and appear in july. The pods are ſhort and ſwelling, and in warm ſeaſons

Digitized by Google

come to maturity in England. The ſtalks decay to the root in autumn.

[Stem very much branched. Stipules ſcarcely any. Leaves on very ſhort petioles, obovate, obtuſe, becoming black in drying. Racemes the thickneſs of a horſe hair, few-flowered [a].

Native of Barbadoes and Virginia.] Mr. Miller ſays that he received the ſeeds both from Virginia and Philadelphia, and that formerly a coarſe ſort of Indigo was made from it in America, before the true plant was introduced there. [He cultivated it before 1759.

17. Stem even, high, dark purple. Leaves like thoſe of *Laburnum*, even, elliptic, ſmooth on both ſides, an inch and half long. Stipules ſcarcely any. Raceme a foot long, pendulous: flowers white, the ſize of thoſe of *Laburnum* [b]. Standard ſhorter than the corolla; filaments quite diſtinct [c].]

Root perennial, ſending up every ſpring a number of leaves in proportion to its ſize: their foot-ſtalks are ſmooth, riſing two feet high, and dividing upwards into three or five branches. The peduncles ſpring immediately from the root, and advance rather higher than the leaves; being terminated by a thyrſe (raceme) of large flowers, which is near a foot in length. The corolla is either white or deep blue. Pods ſwelling, black when ripe, having one row of kidney-ſhaped ſeeds. It flowers in june, and the ſeeds ripen in the autumn.

Native of Virginia and Carolina. [Introduced in 1724, by Mr. Mark Cateſby [x].

18. Flowers ſubſeſſile, yellow. Stipules enſiform, large [y]. — Native of Kamtſchatka. Introduced in 1776, by Hugh Duke of Northumberland [z].

19. Found by Thunberg at the Cape of Good Hope [a].

20. Stem ſhrubby: branches ſtiff, obſcurely angular, leafy, tomentoſe, ſubdivided. Leaves ſcattered, petioled, ovate, the younger ones obovate, twenty-two lines in length, and twelve or thirteen in breadth, quite entire, ſometimes having a ſmall reflexed point, above rugged with very ſhort hairs that are ſcarcely viſible, beneath villoſe but not ſoft or ſilky; the rib and veins beneath have an aſh-coloured nap. Stipules two, awl-ſhaped, ſhorter than the petiole, caducous. Flowers axillary, ſolitary, on tomentoſe peduncles ſhorter than the adjoining leaf, having a ſingle joint near the flower; the rudiment of which is covered with a globular villoſe veil, faſtened to the joint of the peduncle; as the flower increaſes this veil ſeparates at its baſe from the joint, and falls off when the flower is about half opened: being villoſe like the calyx, and of the ſame colour, this veil is not eaſily remarked by an inattentive obſerver, before it begins to ſeparate, and falling off before the flower expands it is ſeldom found in dried ſpecimens, which are commonly gathered when plants are in full flower. Although this ſpecies be named *calyptrata*, yet it is not improbable that the other ſingle-leaved ſpecies may have the *calyptra* or veil at the joint of the peduncle. Calyx villoſe, reflexed, not at all thruſt in. Corolla very large, purple.

21. Stem ſhrubby, round, leafy, even, yellow: branches round, tomentoſe. Leaves ſcattered, except on the outmoſt twigs, where they are ſometimes oppoſite, eleven lines long and ſix broad, quite entire, acuminate with a reflexed point, ſmooth; the younger ones tomentoſe-ſilky beneath, the youngeſt on both ſides; all grooved above, keeled beneath, and coriaceous: petioles ſhort. Stipule awl-ſhaped, tomentoſe, ſcarcely longer than the petiole, on each ſide of the petiole. Flowers at the ends of the branches from the laſt axils of the leaves. Common peduncle the length of the next leaf, and then divided into two one-flowered pedicels, joined by a common articulation; theſe pedicels become gradually thicker towards the upper part, and have a yellowiſh nap on them like the peduncle itſelf. Calyx five-toothed, bell-ſhaped, gibbous, thruſt in at the baſe, cloſely covered with long, curled, reddiſh-yellow ſtrigæ, whence it appears to be longer than the corolla; which itſelf is large, and ſeems to be pale yellow with purple ſtreaks. Germ hiſpid. Stigma capitate [b].

This and the preceding are natives of the Cape of Good Hope.

22. Stem ſhrubby, round, leafy, even: branches almoſt upright, tomentoſe, ſomewhat angular towards their tops. Leaves ſcattered, on ſhort petioles, ten lines long, and four broad, quite entire, rounded at the end with a reflexed point, grooved above and keeled beneath, coriaceous. On each ſide of the petiole an awl-ſhaped tomentoſe ſtipule, twice as long as the petiole. Flowers towards the end of the branches from the axils of the leaves, ſolitary, on peduncles the length of the adjacent leaf, white-tomentoſe; ſeldom two-flowered. Calyx bell-ſhaped, five-toothed, thruſt in at the baſe, of the ſame colour with the peduncle. Corolla purple, with a paler keel. Germ extremely hiſpid. Stigma ſimple, becoming black [c].

Native of the Cape of Good Hope. Cultivated in 1692 by Biſhop Compton, as appears from Plukenet. It flowers from november to january [d].

23. Native of the Cape of Good Hope, where it was found by Mr. Francis Maſſon; and introduced in 1774. It flowers in july and auguſt. Shrubby [e].

24. Stem ſuffruticoſe, looſe, round, leafy, tomentoſe: branches ſhort, ſpreading, more tomentoſe. Leaves ſcattered, on very ſhort petioles, ſix lines long and three wide, quite entire, bluntiſh, above ſmooth and grooved, beneath ſilky-tomentoſe and keeled, fleſhy: the young leaves rufous and ſhining, eſpecially at the edge and beneath. Stipules two, filiform, intrapetiolar, three times as long as the petiole. Flowers from the ends of the branchlets, ſolitary, on a peduncle the length of the leaf next below, rufous-tomentoſe. Calyx bell-ſhaped, five-toothed, thruſt in at the baſe, rufous-hoary on the outſide, but white within; ſegments ſharp. Corolla purple with paler wings. Germ extremely hiſpid. Style terminated by a little head [f]. Native of the Cape of Good Hope.

25. Found at the Cape of Good Hope by Thunberg [g].

PROPAGATION AND CULTURE.

1. 2. The two firſt ſpecies may be raiſed from ſeeds, which ſometimes ripen in this country. They may alſo be increaſed by cuttings and layers. They will bear our climate, if planted againſt a wall, where they may be covered with mats, to protect them from ſevere froſt.

A finer ſight, ſays Mr. Curtis, can ſcarcely be imagined than a tree of this ſort, extending to a great breadth on a wall with a weſtern aſpect, in the Apothecaries garden at Chelſea, where it was planted by Mr. Forſyth about the year 1774, and which at this moment (april 28, 1791) is thickly covered with large pendulous branches of yellow, I had almoſt ſaid, golden flowers; for they have a peculiar richneſs, which it is almoſt impoſſible to repreſent in colouring.]

4. This increaſes faſt enough by its creeping root, in the ſame manner as Liquorice, and being very hardy, may be planted in ſome corner of the garden, at a diſtance from other plants, which it will otherwiſe ſoon overbear. It will thrive in almoſt any ſoil and ſituation.

5. 6. 7. Theſe muſt have the protection of a ſtove; and may be propagated by ſeeds, when they can be procured from the countries where they grow naturally. Sow the ſeeds in pots, plunging them in a good hot-bed, and they will appear in a month or ſix weeks. When fit to remove, tranſplant them into ſeparate pots, filled with ſoft loamy earth, and plunge them into the bark-pit; ſhading them till they have taken new root. They muſt be kept in the bark-pit, and have little water in winter.

[8. 10. 11. 13. 14. 19. 20 to 25. Require the protection of the dry ſtove, or a good glaſs caſe, and may be increaſed by cuttings.]

Digitized by Google

15. 16. 17. May be propagated by ſeeds ſown on a warm border, at the beginning of april, in ſhallow drills. When the ſtalks decay in autumn, take the plants up carefully, and ſet them in a warm border, where they are deſigned to remain; for they do not bear tranſplanting well.

Or the ſeeds may be ſown, and the young plants raiſed in a moderate hot-bed. The firſt winter they may be placed in a common frame, or covered with mats; and the following ſpring, turned out of the pots, and planted in the full ground, where if the ſoil be dry, and the ſituation ſheltered, they will live many years, flowering and producing ſeeds.

DESCRIPTIONS, *&c.*

1. [The Mountain Aſh is an elegant tree, of ſlow growth; the wood tough and cloſe-grained; not very hard; the bark ſmooth and gray; the young branches purpliſh brown. Leaves unequally pinnate: leaflets (five, ſix, ſeven or eight pairs,) ſerrate except at the baſe, ſmooth above, and nearly ſo beneath, except a few fine ſcattered hairs; their under ſide is alſo glaucous: they are ſeſſile, lanceolate, the middle ones are longeſt, and the odd one is rather oblong-ovate: the midrib is channelled, and often purple.] Mr. Miller remarks, that the leaves on the young trees in the ſpring are hoary on their under ſide, but about midſummer the hoarineſs goes off, and thoſe upon the older branches have very little at any ſeaſon. [The flowers are in large, terminating, pubeſcent corymbs, very much branched. Corollas white, with very concave petals. Germ hairy. Styles three or four. Fruit bright red or ſcarlet when ripe, nearly round, the ſize of a large pea, juicy, with an aſtringency. Seeds three, ſometimes four or five[h]. Dr. Smith calls the fruit a pome. Gærtner, who follows Linneus in naming it a berry, ſays that it has five cells, two or three of which are often abortive; the fertile ones are lined with a very thin papery membrane: in each of theſe are two germs, which become two oblong ſeeds, acuminate at both ends, and plano-convex. He reduces it to the genus *Pyrus*; Dr. Smith and Mr. Relhan have followed him. We might thus reduce the genera of ſome natural orders into one, as Scopoli has done in the *Stellatæ.*

Native of the colder parts of Europe, mount Libanus, Siberia, &c. Woods and hedges on mountainous and boggy ſituations in the north of England, in Wales, Scotland and Ireland; flowering in may.] In the ſouthern counties it is ſeldom found of any ſize, but in the northern counties and in Wales there are trees of very large growth. The leaves make a pretty variety when mixed with other trees in plantations. It is alſo handſome when in flower, and in the autumn, when in fruit: but the blackbirds and thruſhes are ſo fond of it, that they devour it before it is well ripe.

[In the Scottiſh highlands, ſays Mr. Gilpin, the Mountain Aſh becomes a conſiderable tree. There on ſome rocky mountains covered with dark pines and waving birch, a few of theſe trees mixing with them have a fine effect. In ſummer, the light green tint of their foliage; and in autumn the glowing berries, which hang cluſtering upon them, contraſt beautifully with the deeper green of the pines: if they are happily blended, and not in too large a proportion, they add ſome of the moſt picturеſque furniture with which the ſides of thoſe rugged mountains are inveſted.

In ancient days, when ſuperſtition held that place in ſociety, which diſſipation and impiety now hold, the Mountain Aſh was conſidered as an object of great veneration. Often at this day, a ſtump of it is found in ſome old burying place; or near the circle of a Druid temple, whoſe rites it formerly inveſted with its ſacred ſhade[i].

This tree may to this day, ſays Mr. Lightfoot, be obſerved to grow more frequently than any in the neighbourhood of the druidical circles of ſtones, ſo often ſeen in North Britain; and ſuperſtitious perſons ſtill believe that any ſmall part of it carried about them, will prove a ſovereign charm againſt all the effects of enchantment or witchcraft. The dairy-

[h] Smith brit. & engl. bot. Relh. Abbot.

maid

Digitized by Google

maid will not forget to drive her cattle to the *ſhealings* or ſummer paſtures with a rod of the Roan-tree, which ſhe carefully lays up over the door of the *ſheal-boothy* or ſummer-houſe, and drives them home again with the ſame. In Strathſpey, they make, on the firſt of may, a hoop with the wood of this tree, and in the evening and morning cauſe all the ſheep and lambs to paſs through it.

In Wales, ſays Mr. Evelyn, this tree is reputed ſo ſacred, that as there is not a church-yard without one of them planted in it, ſo on a certain day in the year every body religiouſly wears a croſs made of the wood, and it is reputed to be a preſervative againſt faſcinations and evil ſpirits, whence perhaps we call it *Witchen*; the boughs being ſtuck about the houſe, or the wood uſed for walking ſtaves [k]. It is curious to obſerve how the ſame old ſuperſtitions have been driven with the ancient inhabitants into the remote corners of our iſland, ſo diſtant from each other as Scotland and Wales.

The wood is tough and cloſe-grained, but not hard. It may be uſed in mill-work, and converted into tables, chairs, ſpikes for wheels, ſhafts, ſcrews for preſſes, &c. The roots are formed into handles for knives, and ſpoons [l]. Beſides the uſe of it for huſbandmen's tools, goads, &c. the wheelwright commends it for being all heart; and if the tree be large, it will ſaw into planks, boards and timber. Our fletchers commend it for bows next to Yew; and it is excellent fuel [m]. The berries dried and reduced to powder make wholeſome bread; and an ardent ſpirit may be diſtilled from them, which has a fine flavour, but is ſmall in quantity. The Scottiſh highlanders make this uſe of them, and ſo do the inhabitants of Kamtſchatka, as we are informed by Gmelin. Infuſed in water, they make an acid liquor ſomewhat like Perry, which is drank by the poorer people in Wales. In the iſland of Jura they uſe the juice of them as an acid for punch. In Germany the fowlers bait ſpringes or nooſes of hair ſuſpended in the woods with theſe berries, to entice the red-wings and field-fares; whence the trivial name of *aucuparia* [n].

This tree is generally known in the ſouth of England, by the name of *Mountain Aſh*, from its growing in high ſituations, and having pinnate leaves like the Aſh; but this name has led ignorant perſons to ſuppoſe that it has an affinity with the Aſh; and even Mr. Gilpin ſpeaks of it as a variety of that tree, whereas it is totally different in every reſpect except a ſmall ſimilitude in the leaves. Gerarde calls it the wild Aſh, Quickbeam or Quicken tree. Evelyn the Quickbeam, Wild Sorb, or Witchen; which is otherwiſe written Whicken, or Whitten. All theſe names, except Aſh and Sorb, are evidently the ſame, and are derived from the ſuppoſed efficacy of this tree in reſiſting witchcraft. In Scotland and the north of England it is called *Roan-tree*, and this name is variouſly ſpelt *Rowne*, *Roddan* and *Rantry*.

2. This is a middle-ſized tree. Leaves lobed in front, pinnate at the baſe, ſerrate, without any ſtipules, ſmooth above, white-tomentoſe beneath. Corymbs terminating, tomentoſe, many-flowered. Flowers white. Styles three, or ſometimes two only. Fruit as in the preceding, but a little larger [o].

Stature and leafing ſomewhat like that of *Cratægus* or *Pyrus Aria*; but the corymb, flowers and three piſtils of *Sorbus aucuparia* [p].

Linneus conſiders it as a new tree produced between theſe two, and making a diſtinct ſpecies. He remarks that the leaves have the ſame texture as in thoſe of *Aria*, and that the outmoſt leaflets are confluent [q].

In the Flora Suecica he relates that it was ſent him by Kalm, and that it occurs only in Finland. It has ſince been found in Thuringia; and in Wales, on the walls of Caſtel Dinas brân in Denbighſhire; but Dr. Smith ſays that a ſpecimen gathered in the latter place was moſt certainly only the *Aria*. He remarks alſo that it may be propagated by the ſeeds, and therefore cannot properly be conſidered as a mule. It was introduced in 1779 by Chevalier Thunberg [r].

3. The true Service is a tree of a middling ſize, not unlike the Mountain Aſh, of very ſlow growth, not flowering till it arrives at a great age; the wood is very hard. Leaves alternate, compoſed of from ſix or ſeven to nine pairs of oppoſite, ſeſſile, ovate or oblong, equal leaflets, with a terminating one of the ſame ſize; all entire at the baſe, ſerrate from about half way to the end, ſmooth above, downy beneath, but that downineſs goes off towards autumn. Flowers in terminating panicles, ſubcorymbed, tomentoſe. Petals cream-coloured, concave with hairy claws. Calyx very woolly. Styles always five, with oblique concave ſtigmas. Fruit pear-ſhaped, reddiſh and ſpotted, extremely auſtere, and not eatable till it is quite mellowed by froſt or time, when it becomes brown and very ſoft. In the middle are five cells, with one ſeed in each [s], as in the Apple and Pear; with which this tree agrees certainly in the fruit, and number of ſtyles; but if general habit has any thing to do in the arrangement of plants, the Service ought not to be united with them.

The fruit is certainly a Pome, Gærtner however, following Linneus and others, calls it a ſubturbinate Berry, an inch long, variegated with green, yellow and red: it has five cells, two or three of which are often abortive, and the fertile ones are lined with a thin poliſhed papery membrane: in each of theſe cells there are conſtantly two germs, but commonly one ſeed only, biggiſh for the ſize of the fruit, lenticular-compreſſed, ruſeſcent.

According to Krocker, this is diſtinguiſhed from the firſt ſpecies by its greater height, harder wood, and later flowering, for it does not come into full bearing before it is ſixty years old, as Gmelin affirms. The branches are more villoſe and whitiſh, the leaves wider, and tomentoſe at the back; they do not ſmell unpleaſantly: the cymes are ſmaller; the calyx is woolly, and the ſegments are very ſmall: the fruit is pear-ſhaped and much larger, being as big as ſome pears; it is yellow mixed with red on the outſide, and within has five cells, with five ſeeds: but Crantz ſays that the ſeeds are ſeldom all perfect.]

Mr. Miller informs us that there are ſeveral varieties of this fruit, differing from each other in ſize and ſhape; ſome are like Catherine Pears, and nearly as large, others are ſhaped like Apples; but both ariſe from ſeeds of the ſame tree. The ſeveral varieties differ in the number of their ſeeds, ſome having three only, others four or five. When it is ſaid therefore that one character of the genus is to have three ſeeds, it muſt be underſtood of the wild tree; but in trees that are cultivated the number of ſeeds is as uncertain as in Apples and Pears.

In Italy, where the Service tree is very common, they have many varieties obtained from ſeeds, but I have not obſerved in the Engliſh gardens more than three, and thoſe are very ſcarce; for the fruit not being eſteemed in England, we have very few large Service trees. There was one in the garden of John Tradeſcant at South Lambeth, near forty feet high, which produced a great quantity of fruit annually, ſhaped like Pears. Some trees of middling growth in the garden of Henry Marſh, Eſq. at Hammerſmith, produced fruit of the Apple ſhape. From theſe many trees were raiſed in the nurſeries near London, but the fruit is ſmall compared with that of Tradeſcant.

Great numbers of large Service trees grow wild about Aubigny in France, whence the late Duke of Richmond brought a great quantity of the fruit, and from the ſeeds raiſed a conſiderable number of young plants at Goodwood in Suſſex.

The true Service is a native of the warmer parts of Europe, where it becomes a large and lofty tree.—[In England, Ray ſays it has been obſerved to grow wild in many places in the mountainous parts of Cornwall, by that ingenious young gentleman Walter

Moyle,

Digitized by Google

Moyle, Eſq. in company with Mr. Stevens of that county. It was alſo found by Mr. Pitts, alderman of Worceſter, in a foreſt of that county; and is ſaid by Dr. Plot, to grow wild in many places of the Morelands in Staffordſhire [t]. Lord Valentia has found a ſolitary tree in the middle of Wire foreſt near Bewdley, the ſame probably that was obſerved by Alderman Pitts [u]. It flowers in may.

The wood is uſed by the turner in foreign countries. Naſh ſays it is valuable for making mathematical rulers and exciſemens gauging-ſticks.

The fruit is auſtere and aſtringent, like a Medlar, but inferior to it. In the ſouth of Europe it is reputed good in the dyſentery and fluxes.]

PROPAGATION AND CULTURE.

All theſe ſorts may be propagated by ſowing their ſeeds in pots ſoon after the fruit is ripe, ſheltering them under a common frame in winter, and plunging the pots into a moderate hot-bed in the ſpring, which will ſoon bring up the plants; and when they are come up, they ſhould be carefully kept clear from weeds, and in dry weather watered; but they ſhould be expoſed to the open air, for the only reaſon of putting them in a hot-bed is to forward the growth of the ſeeds; but if, when the plants are come up, the bed is kept covered, it will draw the plants and ſpoil them. In this bed the plants ſhould remain until the middle of October, at which time the leaves will decay, when there ſhould be a warm light ſpot of ground prepared to receive them, into which they ſhould be planted in rows two feet aſunder, and a foot diſtant in the rows, obſerving to take them up carefully, and to plant them as ſoon as poſſible, that their roots may not dry.

During the ſummer, the ground ſhould be kept conſtantly clear from weeds, and in winter there ſhould be a little mulch laid upon the ſurface of the ground about their roots, to protect them from being injured by froſt; but in the ſpring the ground between them ſhould be dug, burying the mulch therein, in doing of which you muſt be careful not to cut or injure the roots of the plants.

In this nurſery they may continue three or four years according to their growth, when it will be proper to tranſplant them out where they are to remain; the beſt ſeaſon for which is in October; or in the ſpring, juſt before they begin to ſhoot. The ſoil ſhould be warm in which they are planted, and the ſituation defended from cold winds, in which place they will thrive, and produce fruit in a few years.

Thoſe who raiſe many trees of the true Service from ſeeds, will procure ſome varieties of the fruit, from which the beſt may be ſelected, and propagated for the table, and the others may be planted for variety in wilderneſſes or wood-walks, or may be uſed for ſtocks to graft the better kinds upon.

There is a ſort of this with variegated leaves, which is preſerved by ſuch as are curious in collecting the ſeveral ſorts of ſtriped plants, but there is no great beauty in it; it may be propagated by layers, or by being budded on the plain ſort, but they become plain on a very rich ſoil.

The wild ſort ſhould have a moiſt ſtrong ſoil, but will grow in the moſt expoſed places, being extremely hardy, which renders them worthy of care, ſince they will thrive where few other trees will ſucceed.

[If the fruit be ſown in the common ground it will frequently be the ſecond ſpring before it makes its appearance, as in the Hawthorn. It ſhould therefore be diveſted of its pulp and preſerved in ſand.

Mr. Boutcher recommends, when the ſeedling plants have ſtood a year to remove them, and let them ſtand two ſeaſons more; then cutting away all croſs downright or ſuperfluous roots, to remove them into another nurſery, planting them three feet and a half by eighteen inches aſunder; there to remain three years, when they will be of proper ſize to remove where they are to continue.

They may alſo be raiſed from layers, but the trees will neither be ſo handſome nor ſo ſtraight as thoſe which are raiſed from ſeeds.

Leaves drooping flat, heads of flowers in a ſimple ſpike, moſt of them accompanied by leaves, ſtyle not longer than the germ.

DESCRIPTIONS, *&c.*

1. Root perennial, creeping. Stem upright, about three feet high, round, leafy, ſmooth, divided at the top into ſeveral alternate ſlightly flexuoſe flowering-branches. Root-leaves ſword-ſhaped, erect, ſmooth, entire; at their baſe triangular, with their ſides concave or channelled, not flat. Stem-leaves merely concave, and ſheathing at their baſe. Heads of flowers alternate, ſeſſile, many-flowered; the lower female, the upper male, more numerous, and cloſer together. Calyx-leaves ſpatulate, browniſh, ſhorter than the ſtamens. Anthers yellowiſh white. Germ of two cells, one of them generally obliterated and abortive in the fruit. Style ſhort. Stigma long, linear, oblique, downy on one ſide, for the moſt part ſolitary, but ſometimes two. The fruit ripens into brown prickly heads of dry deciduous drupes, by which, as well as its ſpreading roots, the plant increaſes abundantly [x].

Curtis remarks, that the root-leaves are of a deep green colour, almoſt twice the length of the ſtem; and that the ſtem-leaves are about three in number, beſide the floral-leaves, which are about four.

The parts of fructification vary much in number, as is uſual in monoecious and dioecious plants; one of the many reaſons for keeping them in diſtinct claſſes from the hermaphrodite ones.

Common in ditches and along the banks of rivers; flowering in july and auguſt [y]. Having a very ſtrong creeping root, it ſoon fills up a ditch or pond, if ſuffered to remain unmoleſted [z]: the ſmaller brooks are ſoon clogged by it, and it forms dams with other aquatic plants, which arreſt the deſcending ſoil and make iſlands or banks of earth. It is common not only in Europe, but in Barbary, Siberia, and North America.

2. This was conſidered by Linneus as a variety of the preceding; but they were held to be diſtinct by all the old botaniſts, Mr. Hudſon and after him our other Engliſh botaniſts have followed theſe, and Mr. Curtis has ſeveral important diſtinctions. This ſpecies is ſeldom found more than one fourth ſo high as *S. ramoſum*, and yet the flowers are larger in proportion. The leaves incline much more to a yellow colour, and inſtead of being hollow on two ſides near the baſe, they are flat, ſo that a tranſverſe ſection forms a triangle with nearly plane ſides. Each flower-ſtalk ſupports only a ſingle globule of male or female flowers: the lowermoſt (which ſupport female flowers) vary conſiderably in length, being ſometimes more than an inch in length. Pollich remarks this circumſtance, and Mr. Woodward relates that in his ſpecimen, the fruit-ſtalk of the loweſt ball is two inches long, the next one inch, and two above theſe ſeſſile.—The flowers before they blow look yellow, and have none of the blackneſs about them, ſo conſpicuous in thoſe of *ramoſum*. In Engliſh Botany it is remarked, that the calyx is generally green, or at leaſt of a paler brown than in the former: that the ſtigma, as in that is long and linear, not ſhort and ovate as in *S. natans*, to which the preſent ſpecies is in other reſpects perhaps more nearly allied than to *S. ramoſum*: and that it has ſometimes two ſtigmas like that.

Unbranched Bur-reed, though by no means ſo common as the preceding, is not very rare in ponds and ditches. It is found, as Mr. Curtis ſays, only on particular ſpots, eſpecially on heaths and commons, in pools of water made by digging gravel. It flowers in july and auguſt. Lightfoot affirms that this is more common in Scotland than the preceding. He does not diſtinguiſh them ſpecifically, but conjectures that they are different.

3. Root perennial, creeping, with long fibres, running deep into the muddy bottoms of ditches or ſlow ſtreams. Stems aſcending, round, leafy. Leaves linear, narrow, thin and almoſt pellucid, flat; ſheathing and a little channelled towards the baſe, but without any degree of keel or midrib; the lowermoſt long and floating, the reſt gradually ſhorter. Flowers from the boſoms of the upper leaves, in three or four ſolitary little round heads, improperly called aments by Linneus: the loweſt is on a footſtalk: the uppermoſt only, or part of the next, conſiſts of male flowers; the reſt are female. Calyx of three whitiſh leaves. Stamens twice as long. Germ ovate, very ſmooth. Style ſimple: ſtigma oblique, with a fiſſure on the upper ſide. The ſhortneſs of this ſeems the beſt mark of diſtinction between the *natans* and the two former ſpecies. The fruit is a one-ſeeded drupe [a].

Lightfoot remarks, that the ſtalk is about two feet long; the leaves four, a quarter of an inch wide at the baſe, one eighth in the middle, and ending in a point; that the female ſphærules are commonly three, the two lower ones on peduncles, the uppermoſt ſeſſile; males alſo generally three, all ſeſſile; and that when the plant flowers, the ſtalk is raiſed above the water three or four inches, the leaves ſtill continuing to float.

Mr. Woodward ſays, that the flowering-ſtem is very ſlender, and does not riſe above ſix inches out of the water, ſimple with few balls of female flowers, and thoſe not longer than a pea; and that the leaves float on the water to a conſiderable length. Mr. Hudſon conſiders this as a variety of the preceding. Mr. Curtis remarks with reaſon, that ſoil and ſituation often make a great difference in the appearance of plants; but that does not ſeem to be the caſe here.

The *natans* occurs in Cambridgeſhire near Sawſton moor, on Wilbraham moor, and Burwell fen; near Norwich; in Yorkſhire and Weſtmoreland; Scotland and Wales; flowering in july. It ſeems to prefer a muddy or clay ſoil.

however than the corolla. *Anthers* ovate-cordate, placed on the top of the filaments.

PIST. *Germ* ſubglobular, five-cornered, hiſpid, ſuperior. *Style* filiform, ſtraight, hanging down among, and much longer than the ſtamens. *Stigma* truncate, terminated by elongated papillæ.

PER. *Capſule* five-cornered, five-celled, echinate with ſtraight, rigid, hairy briſtles, terminated by a pellucid, ſtraight, pungent ſpine, larger and more pungent at the corners.

SEEDS two, oblong, ſmooth, keeled on one ſide.

ESSENTIAL CHARACTER.

Cal. four-leaved. *Cor.* of four reflexed petals. *Nect.* ſeveral, toruloſe. *Capſ.* angular, five-celled, echinate.

SPECIES.

1. Sparrmannia africana.

Lin. ſpec. ed. Willd. 2. 1160. *ſyſt.* 492. *ſuppl.* 265. *Thunb. nov. gen.* 5. 89. *Retz. obſ.* 5. 25. *n.* 65. *t.* 3. *Curt. magaz. t.* 516.

DESCRIPTION, *&c.*

This beautiful ſhrub grows to the height of ſix feet or more, and is thickly divided into alternate branches, finely clothed with large cordate and lobed pendulous leaves upon erect footſtalks, making a very handſome appearance even in foliage, in which ſtate it much reſembles a *Sida*; its fine umbels of flowers are produced plentifully along the young branches, oppoſite to the leaves, in the ſame manner as in the common ſpecies of *Pelargonium*, which it reſembles much in its inflorescence, the flowers nodding before they are expanded, and becoming erect as they approach maturity. The petals, which are of a ſnowy white, remain but a ſhort time open, being ſoon reflected with the calyx: this is white like the petals, but covered, as is the whole plant except the petals, with fine hairs. The ſingular nectaries ſurround the filaments, which they ſo nearly reſemble, that a ſuperficial obſerver might eaſily confound them; they are very numerous, ſhorter than the purple filaments, of a yellow colour, and toruloſe or knobbed at the upper part: they have no anthers, but purple tips not unlike them. The whole plant abounds with a taſteleſs mucilage [b].

The herb reſembles the *Triumfettas*, and ſtill more the *Commerſonia*; it has the peduncle and inflorescence of the Geraniums, with the fruit of *Hibiſcus*, but prickly as in *Geum*, ſo that it is as it were compoſed of ſeveral different genera [c].

The deſcription in the *Supplementum Plantarum* of the younger Linneus, is in moſt reſpects very accurate, but the petals and nectaries are ſaid to be yellow, which may be a miſtake ariſing from having deſcribed from a dried ſpecimen [d].

The ſynonym, country, and obſervation in Retzius, belong to *Lagerſtroemia* [e].

This ſhrub is native of Africa, near the Cape of Good Hope, in Eſſeboſch and Houtniquas woods, and the ſides of the mountains at Lange Kloof, where it was found by the celebrated traveller whoſe name it bears.

It has been introduced at Kew ſince the catalogue was printed; and has flowered there, and at Meſſrs. Whitley's nurſery at Old Brompton.

PROPAGATION AND CULTURE.

It may be readily increaſed by cuttings, if treated in the ſame manner as ſome of the more tender *Pelargoniums* [f].

SPARROW-WORT. See *Paſſerina.*

SPARTEUM. See *Borbonia.*]

SPARTIUM. (Σπαρτιον of *Dioſcorides*: *frutex ex cujus ramulis* ſpartei *funes contexuntur.*)

Claſſ. 17. 4. Diadelphia Decandria.

Nat. order of *Papilionaceæ* or *Leguminoſæ.*

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, cordate-tubular: at the upper edge very ſhort, below towards the tip marked with five toothlets, coloured, ſmall.

COR. papilionaceous, five-celled. *Standard* obcordate, the whole reflexed, very large. *Wings* ovate, oblong, ſhorter than the ſtandard, annexed to the filaments. *Keel* two-petalled, lanceolate, oblong, longer than the wings, (the carinal margin connected by hairs,) inſerted into the filaments.

STAM. *Filaments* ten, connate, adhering to the germ, unequal, gradually longer: the uppermoſt very ſhort: the lower nine-cleft. *Anthers* oblongiſh.

PIST. *Germ* oblong, hirſute. *Style* awl-ſhaped, riſing. *Stigma* growing to the upper ſide of the top, oblong, villoſe.

PER. *Legume* cylindric, long, obtuſe, one-celled, two-valved.

SEEDS many, globe-kidney form.

ESSENTIAL CHARACTER.

Cal. produced downwards. *Filam.* adhering to the germ. *Stigma* longitudinal, villoſe above.

DESCRIPTIONS, *&c.*

1. Stem ſhrubby, rod-like, branched at the baſe, round, even. Leaves alternate not ſcattered, remote, flatted above, purple at the baſe, with a ſubferruginous patulous tip, erect, a finger's length. Raceme long, erect, terminating, with the flowers alternate, of a tawny colour with a yellow keel. It differs from the next ſpecies in having the tenth ſtamen not diſtinct: the leaves not cluſtered, but ſcattered and four times narrower; the purple colour at their baſe is a very evident mark of this ſpecies.—Native of the Cape of Good Hope, in the ſands[g]. Introduced in 1787, by Mr. Francis Maſſon[h].

2. Branches rugged with the fallen leaves. Leaves very cloſely cluſtered, a finger's length. Racemes terminating. Flowers yellow.—Native of the Cape of Good Hope[i].]

3. Branches ſmooth, flexible, eight or ten feet high: the lower ones have ſmall ſmooth leaves, at the end of the ſhoots of the ſame year, the flowers are diſpoſed in a looſe ſpike, they are large, yellow, have a ſtrong agreeable odour, appear in july, and in cool ſeaſons continue in ſucceſſion to ſeptember. Pods compreſſed, about three inches long, ripening in autumn.

[The leaves have two ſtipules at the baſe; Gerard ſays that they are apparent with the lower leaves only, that they ſpread out before flowering time, and when the flowers are fully open, fall off[k].

[The bees are fond of the flowers; and the ſame qualities which are attributed to the common Broom belong alſo to this, perhaps in an inferior degree, at leaſt as it is found in our gardens. In Languedoc they make a thread of it, and it is there uſed as a green food for ſheep.

Spaniſh Broom is native of all the ſouthern countries of Europe, Spain, Portugal, Italy, Sicily, Carniola, and the South of France: Rauwolff obſerved it in Judea, about Joppa and Rama.—It appears from Turner's herbal (2. 144.) that it was cultivated here in 1562, by Lord Cobham.

There is a variety of it with double flowers[l], which is very unuſual in this natural order.] Miller mentions another variety, which is ſmaller and has narrower leaves, ſmaller and paler flowers, appearing later than the common ſort. It was introduced from Portugal; [but being inferior to the other, does not appear to be worth cultivating.]

4. This has a thick ſtalk, covered with a rugged bark when old; it riſes eight or nine feet high, ſending out many ſlender ruſh-like branches of a ſilvery colour, almoſt taper, which terminate in very ſlender bending ends; theſe have a few narrow ſpear-ſhaped leaves on the lower branches. The flowers are produced in very ſhort ſpikes or cluſters on the ſide of the branches; they are ſmall and white. Pods large ovate, containing one kidney-ſhaped ſeed.

[Stem upright, very much branched, as thick as the thumb, and ſometimes as the arm. Branches round, upright, ſlightly ſtriated, ſlender, ſmooth, bundled, leafleſs. On the younger twigs are a few ſmall lanceolate ſilky leaves. Flowers very numerous, diſpoſed in ſhort diſtinct little racemes along the branches; ſometimes they are aggregate, or even ſolitary: each of them is on a very ſhort pedicel. Calyx ſmall, pitcher-ſhaped, often tinged with purple, ſmooth, three-toothed; teeth ovate, almoſt equal. Corolla white, villoſe with very ſhort hairs. Legume ſmooth, roundiſh, a little inflated, hooked, pulpy within; containing one brown ſmooth ſhining roundiſh ſeed, nearly as big as a garden pea. It is a very handſome ſhrub, remarkable for its numerous ſnow-white flowers[m].

Native of Spain and Portugal. Cluſius obſerved it about Cadiz near the coaſt, flowering in february: Alſo in Aragon abundantly. Oſbeck remarks that it grows like willow-buſhes along the ſhore of Spain, as far as the flying ſands reach, where ſcarcely any other plant grows except the *Ononis repens*, or creeping Reſtharrow. The uſe of this ſhrub is very great in ſtopping the ſand. The leaves and young branches are delicious food for goats. It converts the moſt barren ſpot into a fine odoriferous garden by its flowers, which continue a long time. It ſerves to ſhelter hogs and goats againſt the ſcorching heat of the ſun. The twigs are uſed for tying bundles; and all kinds of herbs that are brought to market are faſtened together with them[n]. Forſkahl found it in Arabia; and Desfontaines in Barbary, on the ſandy coaſt. The Spaniards call it *Retamas*, from the arabic name *Rætam*. It was introduced here in 1690, by Mr. Bentick, and flowers in june and july[o].

5. Stem upright. Branches numerous, ſlender, round, ſmooth, ſlightly ſtriated, having a few tubercles ſcattered over them, below leafleſs. Leaves on the younger branchlets, ſmall, lanceolate, deciduous, ſilky with very ſhort hairs preſſed cloſe. Flowers ſmall, racemed, each on a very ſhort pedicel. Calyx ſmall, pubeſcent, two-lipped, the lower lip longer, five-toothed, the three lower teeth very ſmall. Corolla yellow, ſmall, ſilky: ſtandard almoſt upright, roundiſh, entire, ſhorter than the keel; wings lanceolate, obtuſe, ſhorter than the keel, which is ſomewhat bowed, obtuſe, two-leaved. Legume roundiſh, ſlightly bent in on one ſide, yellowiſh, ſmooth, containing one (ſometimes but ſeldom) two ſeeds[p].

Native of the South of Europe; and of Barbary, near Mayane.—Introduced in 1778, by Monſ. Thouin. It flowers in june and july[q].]

6. Stalks ſtriated, taper, four feet high, ſending out ſeveral branches terminated by ſpines. Flowers in terminating ſpikes, large and pale yellow.

[Stems ruſhy, ſtraight, very much branched. Branches unarmed, divided into others, which are frequent and irregular, green, ſtriated, almoſt naked, withering at the end, truncate. Stipules at the baſe of the branches, ſhaped like the nail, blunt, mortified at the tip, at the ſmaller branches wandering: the lower ones leafleſs. The leaves together with the flowers come out from the ſummits of the branches; they are ſeſſile, ovate-lanceolate, unequal, ſilky, more ſhining beneath, ſhorter than the flowers. Flowers ſolitary, on peduncles coming out from the ſide of the leaves. Calyx two-lipped, ſhort, almoſt equal: upper lip retuſe; lower entire: petals almoſt equal; ſtandard cordate-roundiſh, wide; wings oblong, with linear oblique claws, appendicled at the baſe towards the ſtandard; keel a little longer than the ſtandard, not bending down. All the filaments united. Stigma hooked. Legume oblong, compreſſed, villoſe[r]: according to Linneus, ovate, pendulous, ſinuate on one ſide.

Native of the South of France, the county of Nice, Aragon, and Japan. Cultivated by Mr. Miller in 1768.

7. With its branches and their ramifications into very ſimple filiform attenuated flowering branchlets,

[g] Linn. mant. [h] Hort. kew. [i] Linn. amoen. [k] Fl. prov. [l] Hort. kew.

Digitized by Google

this ſpecies reſembles *S. junceum*. There are no leaves except a ſingle ſmall one, which is linear, at each diviſion of the branchlet; ſoon withering away, and rather reſembling a ſtipule. Bractes to each flower, ſmall, awl-ſhaped. Flowers ſmall, pedicelled, forming a raceme on the ſide of the branchlets. Corolla violet. Legumes ſhort, compreſſed, hoary, two-ſeeded.—Found by Pallas, in the driving ſand of the Wolga deſert[a].

8. This is a ſhrub about three feet high, with a trunk of about a finger's thickneſs, dividing into numerous branches, which are ſomewhat villoſe and ſpreading: the leaves are ſimple, lanceolate, either obtuſe or ſlightly pointed, green above and pale beneath: they are ſcarcely more than half an inch in length: the flowers are yellow and ſweet-ſcented; ſtanding on ſhort footſtalks in a kind of racemes at the tips of the branches: the pods are upright and covered with a whitiſh hairy down[b].

Native of the iſland of Madeira: where it was found by Mr. Francis Maſſon; and introduced in 1777. It flowers from march to june[b].

9. Stems angular, branched. Leaves not hard, longer than ovate leaves, wider on this ſide the end, obtuſe, hirſute, not all ſilky, ſolitary even the loweſt. Peduncles an inch long. Flowers ſmaller by half than in the common Broom, and leſs placed on one ſide. Calyx two-lipped, the upper ſegment two-toothed; the teeth triangular, acute, curved a little; the lower three-toothed. Standard veined, yellow, large, emarginate; the wings alſo are wide, oval, with the hook more apparent; beak of the keel curved, and much more acute than in the common Broom.

Found in Burgundy, and in that part of Switzerland which borders on it as at Roulier and Chaux de Fonds[a]. Introduced into England by the doctors Pitcairn and Fothergill. It flowers here in may and june[y].

10. The whole ſhrub is covered with alternate ſpines, on which the flowers are placed[z]. This renders it quite inacceſſible. The branches and leaves are ſtriated and aſh-coloured, and the latter are a little villoſe. The flowers are yellow and rather large. The legumes are villoſe, flatted, and a little curved. The calyx is ſmall, and has five diviſions[a].

Native of the South of Europe, and of Barbary. Cultivated by Parkinſon in 1640. It flowers in march and april[b].

11. This is a very branching ſhrub. Branchlets ſmooth, ſtriated, ſlender, tubercled, frequently bowed, becoming thorny, flower-bearing. Leaves ſmall, narrow-lanceolate, ſilky with very ſhort hairs preſſed cloſe. The older branches are leafleſs. Flowers numerous, ſolitary or in pairs, on pedicels furniſhed with little bractes. Calyx ſmall, ſilky, the three ſegments lanceolate, the loweſt longer and trifid. Corolla pale yellow, ſize the ſame as in *Geniſta tinctoria*: ſtandard obovate, the length of the keel; wings linear, obtuſe, a little ſhorter; keel ſomewhat bowed, obtuſe.—Native of Barbary, on the hills near La Calle[c].

12. This ſhrub is very much branched. The branches or flowering-twigs are erect, ſlender, ſtreaked or furrowed, hoary in the furrows. Leaves ovate, oblong-ovate and lanceolate, petioled and ſeſſile, ſilvery-tomentoſe or ſilky with hairs preſſed cloſe: there is a knot of two or three leaves or more to each flower. Flowers in long lateral racemes, moſtly pointing one way, and ſo numerous that the ſhrub ſeems wholly covered with them: they are each ſolitary, or at moſt two together, and pedicelled. Calyx ſo ſmall as to be ſcarce viſibly toothed. Standard of the corolla erect not reflex, involute, beautifully marked with purple lines radiating from the baſe; the wings alſo have ſometimes a few of theſe purple lines; the reſt of the corolla is white; the wings are involute, bellying in the middle, but meeting at the tips, to the full as long as the ſtandard, and longer than the keel, but being curved meet it at the tip: keel ſeeming to be of one piece unleſs examined carefully, the two parts not being ſeparable without ſome difficulty. The filament cloſely inveſts the naſcent legume after the flower is paſt. Legume very hairy, about an inch long, pointed; containing two or three ſeeds, ſometimes only one.

The above deſcription was made from the live ſhrub in full flower on the 19th of may 1791.

Desfontaines remarks, that the lower leaves are ternate, the upper ſimple, obovate or linear-lanceolate; the calyx ſmall, truncate, ſilky, two-lobed, the lobes blunt; the corolla white, a little ſmaller than in *S. monoſpermum*, the ſtandard elliptic and quite entire, the wings ovate-lanceolate, obtuſe, a little longer than the keel, which is ſomewhat bowed, compreſſed and two-leaved; the filaments are united below into a half-ten-cleft column; anthers ſaffron-coloured; ſtyle filiform, bowed, acute; germ pubeſcent; legume compreſſed, oblong, very villoſe.

Native of Portugal and mount Atlas.—Introduced about 1770, by Mr. James Gordon[d].]

13. Stalks and branches ſlender, having a few trifoliate and ſingle leaves towards the bottom. The branches have ſix angles or furrows; [or as Linneus expreſſes it, three angles run down along the branches from each leaf; and hence his trivial name.] Flowers ſmall, of a pale yellow colour, produced in looſe ſpikes at the ends of the branches. They rarely produce ſeeds in England.

Native of the Levant. [Cultivated by Mr. Miller in 1759.

14. The common Broom grows from three to ſix feet high or more, very much branched; the branches upright, ruſhy, evergreen, angular, flexible, leafy, ſmooth except the very young ones which are downy. Leaves ternate, ſmall, ovate, acute, downy and edged with ſoft hairs bending inwards; the leaf-ſtalks are alſo ſlightly hairy, and flattened. Flowers axillary, ſolitary or two together, rarely three, nodding, on round ſmooth peduncles, furniſhed on each ſide with a very minute ſtipule. Calyx ſomewhat bell-ſhaped, two-lipped, gaping, even, often purple, faintly toothed, the extremities of the lips withered and brown. Corolla large, handſome, of a fine gold colour, ſometimes tinged with orange or tawny on the outſide, and leſs frequently wholly lemon-coloured: ſtandard nearly round, ſlightly notched at the end, very large, reflexed; wings the length of the keel, ſomewhat oval, on ſhort claws; keel large and deep with a blunt beak, compoſed of two petals, which are rather hooked, and united at the lower edge by an intertexture of very fine ſoft woolly hairs. Stamens four long and ſix ſhort, all united at the baſe into a tube: anthers oblong, ſaffron-coloured. Germ villoſe. Style bent almoſt into a circle, and after flowering into a ſpiral, near the tip hollowed below. Stigma terminating, very ſmall, and forming a little head. Dr. Withering remarks, that the very end of the ſtyle, which one ſhould be inclined to regard as the ſtigma, is not hairy. Legume compreſſed, brown or blackiſh, edged with long ſoft hairs[e]. Seeds ſometimes as many as eighteen or twenty, ſmall, of an oblong elliptic form, compreſſed, gloſſy, dingy yellow, beaked above the navel with a ſhort point: the navel is defended by a white two-lobed or cordate gland, which falls off after it is fully ripe. This umbilical wart or gland is wanting in the ſeeds of the Spaniſh Broom (S. junceum,) at leaſt Gærtner's ſpecimens had it not[f].

Native of Europe, in dry ſandy ſoils; flowering in may and june.

The common Broom merits a place among our flowering ſhrubs, eſpecially the variety with a purple calyx, and the flowers ſtrongly tinged with orange. There is another variety much more hoary than uſual. But even in its common ſtate, ſuch is the profuſion of golden-coloured bloſſoms with which its branches are loaded in ſummer, and ſuch the verdure of its twigs in winter, that it may vie with moſt of the foreign Brooms, and is ſuperior to ſome of them as

Digitized by Google

an ornamental ſhrub. It claims ſome attention alſo as an uſeful plant in rural œconomy and medicine.

It is uſed for beſoms, and from their common name of brooms, one may ſuppoſe that this plant was firſt in uſe for the purpoſe of ſweeping. In the northern parts of Great-Britain it ſerves for thatching cottages, corn and hay-ricks, and as a ſubſtitute for reeds in making fences or ſcreens. In ſome parts of Scotland, where coals and wood are ſcarce, it is ſaid whole fields are ſown with it for fuel.

Bees are fond of the flowers: the flower-buds, juſt before they become yellow, are pickled in the manner of capers: the branches are ſaid to be capable of tanning leather, and of being manufactured into coarſe cloth; when tender, they are mixed with hops in brewing: the old wood furniſhes the cabinet-maker with the moſt beautiful material for veneering.

The twigs, when bruiſed, ſmell diſagreeably, which perhaps may be one reaſon why our Broom is generally rejected by cattle [g]: but they have alſo a nauſeous bitter taſte.

Thomſon alludes to the fondneſs which kine ſhow for broom-fields, which they frequent much during the ſummer heat, probably for the ſake of bruſhing off the ſwarms of flies with its tough yielding branches.

The tops and leaves of Broom are commended for their purgative and diuretic qualities. Dr. Mead relates the caſe of a dropſical patient who was cured by taking half a pint of a decoction of green Broom tops, with a ſpoonful of whole Muſtard ſeed, every morning and evening. The patient had been tapped three times, and had tried the uſual remedies before. An infuſion of the ſeeds, drank freely, has been known to produce ſimilar happy effects: but whoever expects theſe effects to follow in every dropſical caſe will be greatly deceived. I knew this medicine ſucceed, ſays Dr. Withering, in one caſe that was truly deplorable; but out of a great number of caſes, in which it had a fair trial, this proved a ſingle inſtance. Dr. Cullen ordered half an ounce of freſh Broom tops to be boiled in a pound of water, till one half was conſumed; and gave two table ſpoonfuls of the decoction every hour, till it operated by ſtool, or till the whole was taken. It ſeldom failed to operate both by ſtool and urine; and by repeating the medicine every day, or every ſecond day, ſome dropſies have been cured.

The plant when burnt affords a tolerably pure alkaline ſalt; and upon this ſalt the efficacy of the aſhes of Broom in dropſies muſt depend. They were uſed principally on the authority of Sydenham; whoſe account of their good effects have been ſince confirmed by Dr. Monro and other writers [h]. The ſame qualities are attributed to *Spartium junceum* and *Geniſta tinctoria*, probably with equal reaſon.

15. Branches very numerous, round, ſlender, ſmooth, upright, cluſtered, ſtriated, with a few tubercles on them. Leaves on the younger branchlets ſilky, linear or linear-lanceolate, acute, villoſe with hairs preſſed cloſe. Flowers in terminating heads, ſeſſile. Calyx ſilky, ſubbilobed, five-toothed: teeth acute, two upper, three lower. Corolla yellow, ſilky on the outſide: ſtandard as long as the keel, obovate, entire, with a very ſhort claw: wings ſhorter than the keel, which is ſlightly bowed. Legume compreſſed, linear, acuminate, covered cloſely with hoary ſhort hairs. Seeds from three to five, ſmall, compreſſed, ſomewhat kidney-ſhaped.

Native of Barbary, on dry hills near Arzeau, on the ſea coaſt.

16. Stem upright, with numerous ſtriated branches, and ſtout long ſtriated flowering ſpines. Leaves ſmooth or very ſhortly villoſe, mucronate; the upper ones ſimple, lanceolate and obovate, on very ſhort petioles; the lower ternate and obovate. Flowers numerous, ſolitary, axillary, on ſhort pedicels, diſpoſed in looſiſh racemes. Rachis pubeſcent. Calyx three-parted, with acute ſegments, the lower one a little longer and trifid. Corolla yellow, the ſame ſize as in *Geniſta ſpinoſa*, and ſmooth. Germ ſilvery. Legume bowed a little, compreſſed, acuminate, toruloſe, hoary with cloſe and very ſhort hairs preſſed cloſe, containing from eight to ten ſeeds.—Native of Barbary; near La Calle [i].

17. This is a low ſhrub, a foot high, very much branched, diffuſed, rigid, rough with ſpines. Branches trichotomous, many times divided, marked with ſix lines, ſmooth, widening towards the top: branchlets above often five from the ſame joint, round, awl-ſhaped, ſpiny, rigid, yellowiſh at the end. Leaves petioled, oppoſite: the three leaflets are ſeſſile, linear, complicate, ſilky, equal. Petiole the length of the leaves, with a ſpinuloſe ſtipule growing to it at the baſe on each ſide. Flowers from the top of the middle branchlet, ſolitary or in pairs, ſubſeſſile. Bractes four, cordate-acuminate, villoſe, dry, at the baſe of the flowers. Calyx dry, two-lipped, villoſe, ſhorter than the pod: upper lip three-toothed, teeth acuminate; lower with two teeth. Corolla yellow. Legume hirſute, hoary, four-ſeeded.

Found by Vahl on mount Uruel, by Jacca, a city of Aragon [k].

18. Branches ſpreading, ſtriated. Leaves ſmall: leaflets obovate, almoſt equal, ſomewhat pubeſcent beneath. Flowers large, tumid, very deep yellow, with a tawny or orange ſpot at the back of the ſtandard. Seed hirſute [l].

This ſhrub appears three times in the *Syſtema Vegetabilium*: and the ſame ſynonym from Tournefort is given in Reichard's edition and the *Supplementum Plantarum* to all three. In the latter work it is ſaid that the branches are dry at the ends; the buds hoary; the flowers ſometimes three together, on one-flowered peduncles, ſhorter than the flowers; calyx ſmooth; corolla yellow; legumes hairy, compreſſed.

Monſ. L'Heritier refers the *Geniſta* figured in Miller's plates, t. 138. to this ſpecies. He deſcribes it as growing to the height of ſix or ſeven feet, ſending out many ſlender pliant branches, ſo as to form a large ſpreading head: theſe branches being fully furniſhed with flowers in every part, the ſhrub makes a fine appearance during their continuance. He adds that the branches are generally three-cornered, ſpread and turn downward; that the leaves are ſometimes ſingle, and thoſe that terminate the branches end in three points; that the flowers come out ſingly from the axils on ſhort pedicels; that the calyx is ſhort and cut into five parts, and the corolla yellow; that it flowers at the end of april and beginning of may, and the ſeeds ripen in july; that it is a native of Portugal, and he has ſeveral times received the ſeeds from thence.

All are agreed that this ſpecies is a native of that country. According to the Kew catalogue, it was introduced about 1764, by Mr. James Gordon.

Mr. Miller has three ſorts in his Dictionary (n. n. 5, 6, 7.) with ternate leaves and unarmed branches, from Spain and Portugal; which he names *luſitanicum*, *birſutum* and *glabrum*. They have not been adopted by other authors, and may perhaps belong to this ſpecies.

19. Trunk often as thick as the human arm. Branches numerous, unarmed, deeply ſtriated, frequently leafleſs at the top. Leaves petioled: leaflets ſmooth or ſcarcely villoſe with very ſhort hairs. Flowers numerous, aggregate and ſometimes ſolitary, on filiform pedicels. Calyx ſmall, pitcher-ſhaped, two-lobed, with very ſmall teeth, two upper and three lower. Corolla deep yellow, ſhining, a little inflated, the ſame ſize as in *S. ſcoparium*: ſtandard obcordate, the length of the wings and keel; wings large, elliptic, obliquely truncate, clawed; keel rounded at the top, bowed. Filaments bowed, united at the baſe into a column, five ſhorter. Style curved in. Legume flat, linear, many-ſeeded, black when ripe, ſilky-villoſe with ſhort ſilvery hairs. It is allied to *S. patens*, and is perhaps a variety of it: but the legume is almoſt twice as long, and villoſe with much ſhorter hairs, preſſed cloſe.—Native of mount Atlas and in the vallies near Algiers.

20. This is an unarmed ſhrub, with erect ſtriated branches, the younger ones angular. Flowers ſubſeſſile

[g] Curtis. [h] Withering, Woodville. [i] Desfontaines. [k] Vahl. [l] Linn. ſyſt.

at

at the ends of the branches, generally two together, ſeldom one or three. Calyx two-lobed, pitcher-ſhaped, villoſe, membranaceous, five-toothed, two of the teeth ſuperior. Corolla almoſt the ſize of thoſe of common Broom, yellow, ſhining, ſmooth, ſomewhat inflated: ſtandard obovate, quite entire, ſcarcely exceeding the wings and keel; wings lanceolate-linear, obtuſe; keel boat-ſhaped, obtuſe. Filaments united below. Style bowed. Stigma obtuſe. Legume ſmooth, compreſſed, hooked, many-ſeeded.—Native of Mount Atlas near Tlemſen.

21. This is an upright ſhrub, the younger branches of which are ſtriated, pubeſcent, cluſtered, and tubercled. Leaves numerous ſcattered in cluſters: leaflets narrower below, ſilvery-ſilky beneath, reflexed at the edge. Pedicels one-flowered. Calyx ſilky, deeply three-parted: ſegments lanceolate, acute, the lower one longer and trifid. Corolla yellow, the ſize of *Geniſta tinctoria*, villoſe with cloſe-preſſed hairs: ſtandard depreſſed, obovate, a little longer than the keel, with the margin reflexed upwards; wings elliptic, obtuſe, equalling the keel, which is ſlightly bowed. Legume linear, flat, hirſute, many-ſeeded. It is an elegant ſhrub, flowering early in ſpring, and is a native of the mountains of Algiers [m].

22. Native of the Cape of Good Hope, where it was found by Mr. Francis Maſſon, and introduced in 1774. It flowers in april [n].

23. This is a ſilky ſhrub. Leaves alternate, petioled; leaflets linear, villoſe [o]. Native of the Cape of Good Hope. Introduced in 1774, by Maſſon. It flowers in april [p].

24. At firſt ſight this exactly reſembles *S. junceum*, but the leaves are ternate, and the branches grooved; the ends of the branches are often leafleſs. Leaves ſmall. Peduncles from the axils of the leaves, ſeveral, heaped, one-flowered. Flowers white, ſmelling very ſweet, ſmall. Legumes compreſſed, ſmooth, becoming black in drying. It is a valuable ſhrub on account of the abundance of its fragrant white flowers [q].

Native of the Pic of Teneriffe, where it was found by Maſſon, and introduced in 1779 [r].

25. Stems low, with oppoſite four-cornered branches. Leaves oppoſite, ſubſeſſile: leaflets ſeſſile, thin, ſubpubeſcent. Petioles extremely ſhort, but permanent, three-cornered, gibbous, very blunt, thicker than the branchlet to be ſupported. Flowers terminating, in threes, ſeſſile. Bracte acute, deciduous [s].]

In its natural ſtate this is a low ſhrub: when cultivated it becomes much larger, though rarely exceeding two feet and a half in height, but the branches ſpread very much and form a large buſh; they are angular and pliable, and always come out by pairs oppoſite. Leaves narrow and awl-ſhaped, placed round the ſtalk, ſpreading out like the points of a ſtar, whence John Bauhin's name, which Linneus has adopted. Flowers in ſmall ſpikes at the end of the branches; bright yellow, but not more than half the ſize of *S. junceum*, and without ſcent. Pods ſhort and hairy, containing two or three ſmall ſeeds. It flowers in june and the ſeeds ripen in auguſt.

Native of Italy upon the mountains: [alſo of Carniola.—Cultivated by Mr. Miller in 1758 [t].

26. Branches denſe, divaricating, ſmooth, ſtriated, having ſtout, ſtriated, diverging ſpines, ending in a very ſharp prickle. Leaves petioled: leaflets obovate, ſmooth, very ſhortly mucronate, or having no point, a little longer than the petiole. Flowers numerous, pedicelled, axillary, ſolitary and aggregate. Calyx ſmall, membranaceous, with five indiſtinct teeth. Corolla yellow, ſmooth, only half the ſize of the common Broom: ſtandard obovate, quite entire, the length of the wings and keel; wings lanceolate, obtuſe; keel two-petalled, ſlightly bowed, obtuſe. Filaments united. Style inflexed. Legume compreſſed, linear, ſmooth, containing two or four ſeeds [u].]

Stalks five or ſix feet high, ſending out many flexible branches, armed with long ſpines; flowers terminating in cluſters, each upon a long pedicel; corolla bright yellow, appearing in june; pods ſhort, woody, with a thick border on their upper edge, and containing three or four ſeeds.

Native of Italy and Spain near the ſea coaſt; [alſo of the South of France, mount Libanus, and about Algiers.—Cultivated in 1640 by Parkinſon [x].

27. This reſembles the preceding very much, and is diſtinguiſhed from it by its thick legume, covered with a very cloſe wool [y].

Vahl is inclined to think it no more than a variety of the *ſpinoſum*, with which it agrees in every thing, except in the woolly ſhagginеſs of the calyx and legume. He gathered it in Barbary and about Naples. Desfontaines alſo found it in Barbary.

Juſſieu and Lamarck have united *Spartium* and *Geniſta* into one genus, perhaps not without reaſon. They ſeem to form one natural genus, and there are ſcarcely ſufficient artificial characters to diſtinguiſh them.

The Brooms are ornamental, flexible, deciduous Shrubs, of middling growth, with long ruſh-like ſhoots, few leaves, and numerous flowers. Some of them (10. 11. 16. 17. 26. 27.) are armed with ſpines; the reſt are unarmed. They may be divided into three parcels from the leaves; which in the eleven firſt ſpecies are ſimple, in the five next (12 to 16) ſimple and ternate, and in the remainder ternate only. The predominating colour of the flowers is yellow; but in n. 7. they are violet-blue, and in 4. 12. and 24. white. The greater part are natives of the South of Europe, particularly Spain and Portugal, in arid ſterile ſoils: 3 to 6. 9. 10. 12. 14. 17. 18. 25. 26. 27. Many of theſe, and ſome others, are natives of Barbary: 4. 5. 10. 11. 12. 15. 16. 19. 20. 21. 26. 27.—13 and 26 are found in the Levant; 8 in Madeira; 24 in Teneriffe; 1. 2. 22. 23. at the Cape of Good Hope; and 7 in Siberia.]

PROPAGATION AND CULTURE.

3. Spaniſh Broom is eaſily propagated by ſeeds, ſown in the ſpring, upon a bed of common earth, in a ſhady ſituation, where the plants will riſe very freely; they muſt be kept clear from weeds the following ſummer, and in autumn they may be taken up, and tranſplanted into a nurſery, which ſhould be choſen in a warm ſheltered ſituation. N. 7. 9. 10. 12. 18. may be raiſed and treated in the ſame manner.

4. Sow the ſeeds about the middle of april upon a bed of freſh light earth, in drills half an inch deep; the drills not leſs than a foot aſunder, and the ſeeds three inches apart. Remove them at michaelmas, for if ſuffered to ſtand longer, they ſhoot downright roots very deep, and if theſe be cut or broken, when they are grown large, the plants frequently miſcarry.

If the ſeaſon ſhould not be favourable, defer the ſowing, for the ſeeds are ſubject to periſh in the ground by cold or wet. The beſt rule is to ſow them at the ſame time with Kidney-beans.

At michaelmas ſome of the plants may be potted, to be ſheltered in winter, and the reſt may be planted in a warm ſituation and on a dry ſoil; where, if the winter ſhould not prove ſevere, they will ſtand very well. If ſome of the plants are left in the ſeed-bed, they may be ſheltered with mats in ſevere froſt, and ſome mulch laid about their roots.

The above directions will ſerve for n. 5. 6. 8. 11. 13. 15. 16. 17. 19. 20. 21. 26. 27.

25. Sow the ſeeds in autumn in a bed of common earth in rows. The following autumn remove the plants from the ſeed-bed to the places where they are to remain, or into a nurſery for a year or two to get ſtrength: but they will not bear tranſplanting when they are large.

[1. 2. 22. 23. with 8. and 24. are inhabitants of the dry ſtove. Several alſo of the above in the ſecond claſs, require the protection of a greenhouſe in ſevere weather.

DESCRIPTION, *&c.*

This tree riſes by a ſingle ſlender ſtem, like the Palms, and bears all its oval leaves in a pinnated order, on moderate ribs diſpoſed cloſely together about the top, from the centre of which the flower-ſpike riſes; this is very ſpreading, and generally ſhoots ſo as to appear a large blooming pyramid many feet above the foliage. The trunk is ſeldom divided, but is ſo very like what we have already deſcribed under this Engliſh appellation, (Maiden Plumb-tree, Comacladia, p. 124.) both in ſize and appearance, that I could never diſtinguiſh them when out of flower; nor do I yet know which is the true timber tree. This would make a moſt beautiful flowering ſhrub, for it ſeldom riſes above fourteen or ſixteen feet, and its flowering top is generally from four to ſix feet in height. It is frequent in the rocky hills above the ferry, and makes a moſt beautiful appearance in the woods when in bloom[z].

Gærtner deſcribes the fruit as a juiceleſs drupe, ovate-three-ſided, ſmooth, bay-coloured: rind membranaceous-fungous, widening out into rigid brittle wings: ſhell three-celled, ſtony, ovate-acuminate, peduncled with a long rigid briſtle, rounded three-cornered; the corners and cells accompanied by a roundiſh appendicle, prominent above into a dagger point, internally channelled and abounding in a reſinous fluid. Seeds in each cell one, ſubcylindric, acuminate at both ends, on the ſide towards the reſiniferous channel, ſlightly marked with a groove, of a red-ruſty colour, cohering with the outer ſide of the cells. On the ſame tree are other fruits, compreſſed like a lens, having two wings only, and two-celled, but in the reſt of their ſtructure reſembling the others.

Native of Jamaica. Introduced in 1778, by William Wright, M. D.[a]

DESCRIPTIONS, *&c.*

1. Root annual, ſmall, fibrous. Stems numerous, a ſpan or a foot in length, nearly upright or ſpreading a little, round, ſmooth, hairy, clammy and panicled on the upper part, leafy, jointed; joints ſwelling, globular. Stipules in pairs at the joints, very ſhort, the tips of the lower ones reflexed. Leaves in whorls, forming two bundles, about eight in each, the inner ones gradually ſmaller, linear, round, having a deep furrow on the back, blunt and yellow at the tip; the upper ones hairy and clammy. Panicle dichotomous, divaricating, many-flowered. Peduncles one-flowered, pubeſcent, clammy, bracted at the baſe, bent down when the flowering is over. Leaflets of the calyx ovate, obtuſe, concave, hairy, ſcarioſe ſcurfy or whitiſh at the edge. Petals ovate, white, longer than the calyx, a little pointed, faſtened by a ſhort claw [b]. Capſule ovate, ſmooth, ſhining, ſcarcely opening beyond the middle. Receptacle columnar, free, hiſpid with the umbilical chords, a little longer than half the capſule. Seeds numerous, (about ſeventy) ſubovate, compreſſedly three-cornered, ſhagreened with ſcattered raiſed dots, having a groove along the back, and a ridge along the belly, rufeſcent [c]. Smith deſcribes the capſule as being double the length of the calyx; and the ſeeds kidney-ſhaped, gibbous, margined, and finally rugged with tubercles. According to Curtis, the capſule is covered by the remaining calyx; and the ſeeds are rather large, round with a ſmall degree of flatneſs, blackiſh, and if viewed with a magnifier beſet with ſmall, reddiſh, prominent points, and encircled with a manifeſt ring. Gærtner ſays that the capſule is ſix-valved, but ſurely that is not the natural number.

The number of ſtamens is by no means conſtant in this and other kindred genera. Mr. Curtis has not found this plant to vary unuſually in this reſpect. Dr. Smith ſays it varies, but ſeldom, with five ſtamens. This has made ſome confound it with the next ſpecies; which by others has been conſidered as a variety only of this. Pollich affirms that *Spergula arvenſis* has often five, ſix or ſeven ſtamens: Scopoli, that it has five, ſeven or eight, as well as ten: Withering, that it has frequently fewer than ten in the autumn; which is certainly the caſe in ſome other plants. The Biſhop of Drontheim ſays that he has not obſerved any plant in which the number of ſtamens varies ſo much as in this, having obſerved from five to nine and very few with ten, on the ſame individual.

Native of Europe, in ſandy ſoils; alſo of Barbary and Siberia. It flowers here from july to ſeptember.

The inhabitants of Finland and Norway make bread of the ſeeds, when their crops of corn fail. Poultry and birds in general are very fond of the ſeeds. In ſome parts of Holland, Brabant, Flanders, Germany, &c. they ſow great quantities to feed their cattle with the plant, and it is reputed very nutritious. It has been recommended for cultivation in England, but we have fortunately better crops for ſandy lands, ſuch as Rie, Peas, Tares or Vetches, Buckwheat, Carrots, &c.]

Mr. Miller ſays, the chief uſe that is made of Spurrey abroad is for feeding ſheep and cattle in winter, when the common graſs is eaten bare. It is ſaid that it makes cows yield excellent butter, that mutton fed on it is well taſted, and that it cauſes hens to lay abundance of eggs.

[Spurrey, and Chickweed, ſays Dr. Anderſon, are by many thought to cauſe cows to give an extraordinary quantity of milk; that cattle prefer it when green, to almoſt any other plant, and ſheep are exceedingly fond of it. Though cultivated in Holland as a uſeful plant, it is in ſome parts of Scotland a very pernicious weed among corn crops, particularly in ſpongy ſoils. It is ſometimes called *Yarr* there [d]. In Norfolk they call it *Pickpurſe*, which ſhows their contempt of it, and *Sandweed* [e].

2. This has all the habit of the preceding, but it is ſmaller, and has fewer, leſs fleſhy leaves. The margin of the calyx is ſcarcely ſcarioſe. The number of ſtamens is five. The ſeeds are flatted, even, and have a widened, membranaceous, white rim [f].

If the difference between theſe two plants, ſays Mr. Curtis, were to depend ſolely on the number of its ſtamina, we ſhould be ready to conſider them as the ſame; but Ray founds his ſpecific difference on characters leſs ſubject to variation: the leaves at the joints, he obſerves, are fewer and thicker, the plant flowers early and ſoon goes off. Theſe circumſtances are noticed by French botaniſts, and by Ruppius. The difference in the ſeeds are remarked by Moriſon, Dillenius and Villars; the latter of whom ſays it is eaſily diſtinguiſhed, not by the number of ſtamens, but by its blackiſh flatted ſeeds, bordered by a little membrane.

Native of Germany, France, Spain, and Ireland; where it was obſerved by William Sherard, LL. D. Conſul at Smyrna, in ſandy grounds.

Dr. Smith informs us, that Linneus had it from Loefling; and that he has admitted it into the Britiſh Flora entirely on the authority of Dillenius. Some Engliſh botaniſts have miſtaken the *arvenſis* with fewer ſtamens than common for this ſpecies.]

Mr. Miller affirms, that both ſpecies are equally cultivated in Holland and Flanders for feeding cattle; [and Moriſon ſays they are ſo alike that they cannot be diſtinguiſhed but by the ſeeds.

3. Root perennial, fibrous. Stems ſeveral, four inches or more in length, procumbent, but ſometimes

[b] Curtis, Smith. [c] Gærtner.

nearly

Digitized by Google

nearly upright, after flowering often creeping, ſimple or little branched, leafy, round, ſlender, ſmooth or ſparingly haired; the hairs appearing globular at top when magnified, having numerous joints which are ſwelled. Leaves next to the root numerous, forming a tuft, of a beautiful dark green colour, about an inch in length, ſomewhat fleſhy; the lowermoſt ſtem-leaves a little longer than the radical ones, connate, and ſometimes indiſtinctly ciliate at the baſe; the upper ſtem-leaves very ſhort, from their axils producing ſmall tufts of leaves, the rudiments of branches. Flowers white, large in proportion to the ſize of the plant, at the ends of the ſtems and branches, on upright peduncles, about half an inch in length. Calyx-leaves ovate, obtuſe, keeled, nerveleſs, ſmooth, or ſlightly hairy. Petals twice the length of the calyx, rounded ovate, entire. Capſule, ſmall, ovate, half as long again as the calyx. Seeds numerous, very minute, blackiſh[g].

This elegant little plant recommends itſelf to our notice by the beauty of its verdure, and the delicacy of its flowers; the largeneſs and pure whiteneſs of which, joined to its place of growth, ſerve to diſtinguiſh it from thoſe plants which have ſome reſemblance to it in the foliage. It is found in the greateſt part of Europe, in moiſt ſituations, frequently among herbage, and ſometimes out of walls, rocks or ſtones. It flowers in july and auguſt. About London it is a ſcarce plant; but in the north of England it is very common on the borders of rivulets, and generally grows more upright than with us. Mr. Curtis obſerved it growing out of the wall by the Thames ſide, in ſeveral places betwixt Lambeth and Putney: alſo on Hounſlow-heath[h]. Mr. John Goodyer obſerved it, auguſt 12, 1626, plentifully on the boggy ground below the red well of Wellingborough in Northamptonſhire: Dr. John Sibthorp, on Shotover hill, and near Stow wood in Oxfordſhire: Dr. Abbot, at Ampthill and Stevington, in Bedfordſhire: on Hinton and Teverſham moors, Gamlingay, &c. in Cambridgeſhire: boggy ground in Sutton park, Warwickſhire, by Dr. Stokes: bogs about Settle, and other places in the north, by Mr. Curtis: in the bogs on Chorley foreſt, and Beacon hill, Leiceſterſhire, by Dr. Pulteney: on Hampſtead heath and Harefield moor, in Middleſex. In Dorſetſhire not uncommon, moſt plentifully by the Avon; in the marſh between the town and the river at Ringwood; Dr. Pulteney. Side of the lake at Llanberris, by Mr. Aiken. In Scotland, but not very common, in wet paſtures, and on the ſides of lakes and marſhes.

4. Root perennial. Stems decumbent, branched, leafy, round. Flowering-branches aſcending, ſimple, leafy, few-flowered, ſubflexuoſe, with the joints ſwelling a little, ſmooth. Leaves briſtle-ſhaped, connate with a membranaceous baſe, ciliate towards the baſe, ſurface ſmooth; the younger ones in axillary ſolitary bundles. Flowers terminating and lateral ſolitary white, the ſize of *Stellaria holoſtea*. Bractes like the leaves but ſhorter, naked. Peduncles filiform, ſmooth. Calyx-leaves lanceolate acute three-nerved ſmooth membranaceous at the edge. Petals obovate ſcarcely longer than the calyx. Five ſtamens the length of the petals, and five ſhorter. Anthers roundiſh. Germ ovate, obtuſe, five-grooved. Styles ſpreading, ſcarcely longer than the ſtamens.—It is a handſome plant, agreeing very much with the Arenarias, except in the number of ſtyles. It has more affinity to *Spergula nodoſa* than to *ſaginoides*, to which its ſynonyms are often attributed by Engliſh botaniſts.

Native of Siberia, and found by Steller between Jacutz and Ochotz[i].

5. Stem procumbent, two inches high. Leaves linear, in bundles at the joints. Peduncles quite ſimple, very long, lateral without bractes. Flowers drooping[k].

Root perennial, fibrous. Herb entirely ſmooth. Stems decumbent, ſomewhat branched, an inch and half long, leafy, round, jointed, upright at the top. Leaves connate, acute. Peduncles for the moſt part terminating, erect, one-flowered, round, naked, almoſt the length of the ſtems. Flowers drooping, white. Calyx-leaves ovate, obtuſe, even, almoſt nerveleſs, gibbous at the baſe. Petals roundiſh, obtuſe, quite entire, ſhorter than the calyx. Stamens ten, ſcarcely longer than the petals. Capſule ovate, twice as long as the calyx. Seeds kidney-ſhaped, brown, not margined.—Swartz found only five ſtamens[l].

Native of Sweden, Switzerland, France, Siberia, Scotland, on mountains. It was found on Ben Lawers, a mountain in Scotland, in 1794, by Mr. J. Mackay.

6. Root perennial fibrous. Stems ſeveral, an inch or two in length, procumbent and rooting, then upright, branched, leafy, roundiſh, ſmooth, (according to Curtis, covered with ſhort glandular hairs, ſcarcely viſible.) Leaves connate, about half an inch in length, ſharp and terminated by a whitiſh point or briſtle, of a deep green colour, ſomewhat ſhining and rather fleſhy, on the upper ſide ſmooth, on the under and at the edge hairy, the hairs terminated by little glands: ſtem-leaves ſhorter, flattiſh, and tending ſomewhat one way. Peduncles terminating and axillary, one-flowered, more or leſs hairy, an inch or more in length, of a browniſh purple colour. Flowers drooping a little. Calyx-leaves ovate, obtuſe, ſomewhat keeled, hairy and inclined to clammineſs, membranous at the edge. Petals white, length of the calyx, roundiſh, entire and ſpreading. Stamens commonly five, but ſometimes ten. Capſule little longer than the calyx, five-valved. Seeds numerous very ſmall, kidney-ſhaped, compreſſed, pale-brown girt with a black line, ſcarcely margined; when magnified appearing dotted[m].

This plant was taken for the *laricina* of Linneus by Hudſon and Lightfoot, and for the *ſaginoides* of the ſame author by Curtis: but the latter is more branched, has ſwollen knots at the joints of the ſtems, with a remarkable contraction juſt under the knots; it is alſo a larger plant, is deſtitute of hairineſs, and its flowers have always ten ſtamens. The *laricina* has the leaves in oppoſite pairs, with bundles of young leaves or branches in the axils. The peduncles are ſmooth and furniſhed with floral leaves. The calyx-leaves are three-fibred; the flowers much larger, and the ſtamens always ten[n].

Wulfen's plant, deſcribed in Jacquin's collectanea is probably this, though the petals are ſaid to be bigger than the calyx, whereas they are really ſmaller[o].

Linneus certainly confounded this plant with *Sagina procumbens*.

Native of Denmark, Sweden, Germany and Britain; on ſandy commons, and dry gravelly paſtures. Not uncommon on Putney heath, and about Coomb wood. On Bagſhot heath. Cobham and Eſher. On Uxbridge moor. In Dorſetſhire, Devonſhire and Cornwall. In Scotland, near Forfar and between Dundee and St. Andrew's, and in the Iſle of Bute. It flowers from june to auguſt.

7. Stems procumbent, round, knotted: at each knot a pair of linear-ſubulate leaves, connate next the knots, ſhining green, curved in; each pair putting forth on one ſide a bundle of leaves. The extremities of the branches produce a bundle of leaves, which is the rudiment of a new ſtem, and a one-flowered peduncle longer than the new branch, being near two inches in length. Calyx-leaves ovate, with a white membranaceous margin, neither acute nor obtuſe. Petals ovate, marked with lines, not emarginate, obtuſe, white. Filaments ſhorter by half than the corolla. Anthers pale whitiſh purple. Sometimes the flowers have ſix ſtyles.

Native of Piedmont, in alpine paſtures[q].

Allioni took this for the *ſaginoides* of Linneus, but Willdenow regards it as a diſtinct ſpecies. Allioni gives to this that ſynonym of Vaillant which Linneus attributes to his *ſaginoides*, and we have given to *ſubulata*. He alſo gives Haller's *Alſine, n.* 862, as another ſynonym.]

PROPAGATION AND CULTURE.

The uſual time for ſowing the ſeed of Spurrey for feeding cattle, is in july or auguſt, that the plants may acquire ſtrength before winter. As Spurrey will grow on the pooreſt ſand, it may be cultivated in many places to good advantage, where no graſs will thrive well; and by feeding it off the ground, the dung of the cattle or ſheep will improve the land.

For ſaving the ſeeds, they ſhould be ſown in april, that they may ripen in auguſt. The crop muſt be cut before the heads are quite brown, otherwiſe the ſeeds will ſoon ſcatter.

About twelve pounds of ſeed is ſufficient to ſow an acre. Harrow the ground well before the ſeeds are ſown. In the Low countries, this plant ſucceeds a crop of corn. The ſecond ſort is now much cultivated in Flanders; for though it is a much lower plant, they eſteem it to be ſuperior to the other.

[SPERGULA. See *Alſine*, *Arenaria*, *Gypſophila*, *Holoſteum*, *Limoſella*, *Linum*, *Pharnaceum*.]

SPERMACŌCE. (*So named by Dillenius, from* σπερμα, *a ſeed; and* ακωκη, *a ſharp point: theſe plants having prickly ſeeds.*)

DESCRIPTIONS, &c.

1. This plant grows to the height of two feet and a half. The ſtalks are ſtiff, a little angular, and covered with a brown bark; the branches come out by pairs. There are two leaves at each joint placed oppoſite, two inches long, and almoſt a quarter of an inch broad; between theſe come out three or four ſmaller leaves, which ſtand in whorls round the ſtalks; they are ſmooth, and have one ſtrong nerve or rib in the middle. The flowers grow in ſlender whorls toward the top of the ſtalks; they are ſmall, white, and ſeſſile, having a whorl of leaves cloſe under them: theſe are ſucceeded by two oblong ſeeds, having ſmall horns, and ripening in the calyx.

Digitized by Google

[Capſule inferior, ſmall, rough-haired, crowned with the four teeth of the calyx, cruſtaceous, rigid, two-celled, not bipartile: one cell cloſed, the other opening to the middle, with a one-toothed valve. Seed in each cell one, ſmall, elliptic, ferruginous, on one ſide convex and ſmooth, on the other concave by reaſon of the edges being rolled together into a belly [r].

It is an annual plant, native of Carolina, and the Weſt Indies, where it is very common.—In Jamaica it is found only in the woods; and is there obſerved to be ſometimes upright and ſometimes a climber; when erect, it generally riſes to the height of two or three feet; but when it is aſſiſted by the neighbouring ſhrubs, it grows commonly to twice or three times that length. It is called there Iron-graſs [s].

Swartz obſerves, that the ſeeds when unripe are like a capſule and two-celled; but when ripe, are ſeparable, roundiſh, two-toothed with the permanent calyx and rough-haired. It varies with a ſmooth and pubeſcent ſtem, ſtiff and more looſe; with narrower and wider leaves; with whorled and ſubſolitary flowers.

Cultivated in 1732 by James Sherard, M. D. It flowers from june to auguſt [t].

2. This is a herbaceous plant, riſing with ſeveral tetragonal knotty branching ſtems the length of two or three feet; the leaves are oppoſite, ovate, rough, entire, and terminated by a long point: they are diſpoſed in a cruciate direction from each of the knots or joints: the flowers are white, and are borne in ſeſſile groupes or pacquets from the boſoms of the leaves: the calyx is downy, and the anthers long and bilocular.

This ſpecies is a native of Cayenne, growing by pathways and in open plains.

3. This differs from the preceding in having the ſtems lower, ſtraight and ſimple; the leaves ſmaller and green; the ſtipule ſhorter and leſs ciliate; the flowers ſmall and blue; and a little fruit.—Native of Cayenne and Guiana by way ſides.

4. This differs from the Spermacoce alata of Aublet in having a hexagonal flexuous ſtem, by which it ſpreads on the neighbouring plants: the leaves are alſo ſhorter and leſs ſharp: the flowers are borne at the extremities of the branches and are of a blue colour.

Native of Cayenne and Guiana on the banks of rivers [u]. Stamens didynamous, two longer than the corolla [x].

5. This differs from the preceding in having the ſtems hexangular and ſcattered over the neighbouring plants; the leaves ovate ſmaller and petioled.—Native of Guiana, on the banks of rivers.

6. This ſpecies has proſtrate or decumbent ſtems, which are branchy and furniſhed with oppoſite green, ſoft, glabrous, ſeſſile, ovate, and pointed leaves: flowers blueiſh.—Native of Guiana, on the banks of rivers.

7. A perennial ſpecies, with ſeveral branchy and knotty ſtems, the diviſions of which proceed ſometimes from the right and ſometimes from the left of the boſoms of the leaves: flowers ſmall and blueiſh. Native of Guiana, growing about the borders of rivers [y].

8. Stem four-cornered, ſmooth, purpliſh, even, aſh-coloured at the top with very ſhort hairs viſible only with the naked eye. Branches axillary, alternate, of the ſame ſtructure with the ſtem, terminated by three leaves. Leaves ſpreading very much, an inch and half long, remote, cluſtered at the top, indiſtinctly nerved on the upper ſurface, on the lower paler, nerved, appearing hairy on the nerves when examined with a magnifier, but ſcarcely rugged. Petioles very ſhort. Stipules multifid, with ſix or ſeven briſtle-ſhaped erect ſegments. Flowers from one of the axils, collected into a round head, ſeſſile, ſomewhat villoſe, about twenty-four; in the oppoſite axil a branchlet or the rudiment of one. Segments of the calyx ovate [z].

Native of Cayenne and Guiana. Found both by Aublet and von Rohr.

[r] Gærtner. [s] Browne. [t] Hort. kew. [u] Aublet. [x] Willdenow. [y] Aublet. [z] Vahl.

The leaves in the ſpecimen of the latter are larger than thoſe in the figure of the former, but the plants were gathered in the ſame place by both [a].]

9. Stem ſhrubby, three or four feet high, ſending out a few ſlender branches, with narrow leaves on them, not ſo long as thoſe of the firſt ſort; they are ſmooth, of a light green, and ſtand in a kind of whorl round the ſtems, two being larger than the others in each whorl. The flowers grow in thick globular whorls towards the top, and one terminates the ſtem; they are ſmall and very white. The ſtamens ſtand out above the tube.

[Stem rather herbaceous, only a little ſhrubby at the baſe, erect, a foot high, ſtiff, four-cornered. Branches oppoſite, decuſſated, faſtigiate, four-cornered. Leaves oppoſite, decuſſated, lanceolate-linear, with a middle nerve, entire, even on both ſides. Branchlets axillary, length of the leaves, oppoſite. Stipules connate, membranaceous, with whitiſh briſtles. Whorls of flowers embracing, ſmall, white, cluſtered very cloſe together. Calyx ſuperior, minute, with two teeth, on the branches with three or four. Tube of the corolla very ſhort, four-cornered: border four-cleft, erect, minute. Filaments ſtanding out, faſtened to the middle of the tube: anthers incumbent, whitiſh. Germ ovate, ancipital: ſtyle ſhort, emarginate at the top or ſubbifid. Seeds naked, compreſſed, bipartile, crowned, ſmooth, black [b].

Native of Jamaica and Africa. Browne ſays, this little buſhy plant is frequent in the low and hilly lands of Jamaica; that it branches very much, is adorned with many ſmall leaves, and bears all its flowers at the upper joints of the branches.

Swartz remarks, that when it is in flower, it ſmells like Melilot.

Cultivated in 1732, by James Sherard, M. D. who had the ſeeds from near the river Gambia in Africa. It flowers here from june to auguſt [c].

10. Stem herbaceous, four-cornered, tomentoſe, with long joints. Branches oppoſite. Leaves petioled, quite entire, hiſpid, with the nerves underneath tomentoſe. Calyx minute, four-toothed. Fruit two-ſeeded, four-toothed. It was found in Sumatra by Wennerberg [d].

11. Stem herbaceous, erect, four-cornered with the corners hairy, branched. Leaves ſubſeſſile, oppoſite, an inch long, quite entire, nerved, very rugged eſpecially beneath, the four uppermoſt approximating, appearing to have a few hairs ſcattered over them when examined with a microſcope, veinleſs, obliquely nerved, the lower marked with lines along the nerves, ſubciliate at the edge. Membrane of the ſtipules having five hairy briſtles on each ſide. Flowers ſeveral on each ſide in every axil.

Native of the Weſt Indies.

This would appear to be the ſame with the *hirta* of Linneus, if the leaves were rough-haired; but the hairs not being diſcoverable without a magnifying glaſs, and the ſtamens not being longer than the corolla, it is perhaps a diſtinct ſpecies, and ſeems to differ in having the leaves ſcarcely villoſe. The *aſpera* of Aublet is referred to this on the authority of von Rohr, though his figure has lanceolate and longer leaves [e].

12. Stem herbaceous, from one to two feet high, four-cornered, ſtiff, ſtriated. Branches erect, four-cornered, with the angles rough-haired. Leaves ſubſeſſile, entire, nerved, rough-haired. Stipules connate, membranaceous, briſtly at the edge. Flowers ſeſſile, ſmall, white. Calyx four-toothed, very ſhort. Tube of the corolla round, funnel-ſhaped: border four-parted, reflexed. Filaments ſtanding out: anthers blue. Germ hiſpid: ſtyle length of the ſtamens, bifid at top: ſtigmas blue, reflexed. Seeds two covered and united by a ſkin, crowned with the teeth of the calyx, rough-haired; when ſtripped of the ſkin black and ſmooth [f].

Annual. Native of Jamaica: common in all the fields in Liguanee.

According to Browne, it ſeldom riſes above twelve

[a] Vahl. [b] Swartz. [c] Hort. kew. [d] Retz. [e] Vahl. [f] Swartz.

Digitized by Google

or fourteen inches, and is eaſily known by its oblong leaves and arched veins.

13. This ſpecies was confounded with the preceding by Linneus; it is diſtinguiſhed however by its more ſimple ſtem; oblong leaves, the uppermoſt in fours; its villoſity; the whorls of flowers, and ſhorter ſtamens within the throat of the corolla.—Native of Jamaica. Annual[g].

14. Root annual. Stem herbaceous, erect, obſcurely four-cornered: lower branches oppoſite. Leaves oppoſite, ſubpetioled, rugged on both ſides, thickiſh, flexuoſe, ſomewhat oblique, with a ſmall reflexed point. Stipule connecting a pair of leaves on each ſide, ſcarioſe, truncate, with five diſtant briſtles the length of the ſtipule itſelf. Flowers axillary, ſeſſile, two or three. Calyx ſuperior, with four lanceolate patulous leaflets. Corolla violet-coloured, turbinate-campanulate, half-four-cleft, erect, larger than in the other ſpecies. Stamens purple, length of the corolla. Style declined. Stigmas two, blunt, recurved[h]. The pericarp is manifeſtly one-capſuled divided into two cells[i].

Native of Ceylon: and the Eaſt Indies. Introduced in 1781, by the Right Hon. Sir Joſeph Banks[k].

15. This is diſtinct from all the ſpecies by its ſmall orbicular obtuſe leaves. It is very rugged. Stems ſeveral, four-cornered, ſimple or but little branched, diffuſed. Corolla large, funnel-ſhaped, three times as long as the calyx. Stamens longer than the tube.

Native of the Eaſt Indies. If this be the Tardavel of the Hortus Malabaricus, the figure is a bad one. The deſcription ſeems to belong to the preceding ſpecies[l]. Perennial.

16. Root annual. Stem herbaceous, red, round, channelled on every ſide. Branches rod-like, procumbent. Joints thick. Leaves oppoſite, ſubpetioled, alternately marked with lines eſpecially beneath. Inſtead of ſtipules there is a tranſverſe many-awned membrane uniting the leaves. Flowers white, narrow.—Native of the Eaſt Indies[m].

17. Root annual. Plant upright, half a foot high, ſtiff, rugged at the angles. Branches alternate, ſhorter. Leaves oppoſite, ſubpetioled, ſomewhat rugged, connected by a ciliate membrane. Flowers white, in narrow whorls.—Native of the Eaſt Indies[n].

18. Stem herbaceous, four-cornered, ſomewhat villoſe eſpecially at the corners, aſh-coloured at the tip. Leaves ſubpetioled, ſharp at both ends, rugged at the edge, villoſe on both ſides, obſcurely nerved, little paler beneath, four under the terminating whorl; and two ſmall ones at each axil. Stipule a multifid membrane; the ſegments briſtle-ſhaped. Flowers many, a little longer than the ſtipules; the terminating whorl is globular and a little larger than the others. Calyxes villoſe and aſh-coloured. Stamens longer than the corolla: anthers blue. It ſeems to be allied to the preceding, but differs from it in having the ſtem and leaves villoſe, and the ſtipules bigger.

Native of Cayenne, where it was found by von Rohr[o].

19. Stems herbaceous, angular, weak, diffuſed. Leaves reflexed. Peduncles lateral, oppoſite, leafleſs. Flowers in bundles or in a ſimple umbel, with a many-leaved involucre longer than the umbel. Stamens ſtanding out, longer than the corolla.—Native of the Eaſt Indies[p].

20. Stem herbaceous, almoſt ſimple, ſubdivided at the baſe, hard, leafy, four-cornered, rugged, a foot high. Leaves oppoſite and decuſſated, ſubſeſſile, lanceolate-linear, acuminate, nerveleſs (except the middle.) Nerves and margins toothletted backwards, and ſomewhat ſpinuloſe. Flowers in a ſort of globular axillary whorl, involucred with the ſtipules, cluſtered, white. Stipules membranaceous, briſtly at the edge, rigid. Calyx two or four-toothed; teeth linear, longer than the corolla. Tube ſhort: border four-cleft, with ovate ſegments. Filaments included. Anthers whitiſh. Style bifid. Stigmas erect, included[q].

[g] Swartz. [h] Linn. mant. [i] Murray. [k] Hort. kew. [l] Willdenow. [m] Linn. ſuppl. [n] Idem. [o] Vahl. [p] Linn. ſpec. [q] Swartz.

Browne ſays, it riſes generally by a ſimple upright ſtalk to the height of fourteen or ſixteen inches, having from ſpace to ſpace lanceolate, oppoſite, embracing leaves. Flowers numerous, white, gathered into compact axillary heads that grow gradually larger and more diſtinct as they draw nearer to the top.

Native of Jamaica, where it is common in the lower ſavannas about Kingſton.]

PROPAGATION AND CULTURE.

Sow the ſeeds on a hot-bed, and when the plants come up tranſplant them on to a freſh hot-bed to bring them forward, and afterwards treat them in the ſame way with other tender plants from the Eaſt and Weſt Indies. If they are placed in a ſtove, they will live through the winter, and produce good ſeeds the following year.

SPHÆRANTHUS. (*From* σφαιρα, *a ſphere*; *and* ανθος, *a flower. Globe-flower.*)

Lin. gen. n. 998. *Reich. n.* 1083. *Schreb. n.* 1352. *Vaill. act. gall.* 1719. *t.* 20. *f.* 12. *Juſſ.* 176. *Gærtn. t.* 164.

Claſſ. 19. 5. Syngeneſia Polygamia Segregata.

Nat. order of *Compoſitæ Capitatæ. Cinarocephalæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Common* globular, imbricate: *ſcales* acuminate, permanent, clothing the univerſal receptacle all round.

Perianth partial many-flowered, five-leaved, within each ſcale of the common calyx ſolitary, compoſed of linear, equal, erect leaflets.

COR. Partial *Corollets* hermaphrodite few (three) in the diſk; *Females* in the ray commonly five.

Proper of the Hermaphrodite one-petalled, funnel-ſhaped, with a five-cleft patulous border.—*Female* awl-ſhaped, tubular, with a very ſmall trifid cloſed mouth.

STAM. in the Hermaphrodites: *Filaments* five capillary, very ſhort. *Anther* cylindric, tubular, longer than the corolla.

PIST. in the Hermaphrodites: *Germ* waſting. *Style* longer, thicker. *Stigma* quite ſimple.—In the Females: *Germ* oblong. *Style* briſtle-ſhaped, length of the ſtamens. *Stigma* two-parted.

PER. none. *Calyx* unchanged.

SEEDS in the Hermaphrodites none: in the *Females* ſolitary, oblong, naked.

REC. *Common* ſcaly: *Partial* naked.

ESSENTIAL CHARACTER.

Cal. eight-flowered. *Cor.* tubular hermaphrodite and indiſtinct female. *Rec.* ſcaly. *Down* none.

Leaves decurrent oblong quite entire, heads cordate-ovate, ſubſeſſile terminating.]

DESCRIPTIONS, &c.

1. Stem herbaceous, about a foot high, which rarely branches out. Leaves about three inches long, and an inch broad in the middle, of a deep green, and alternate. The peduncles come out from the ſide of the ſtalk, oppoſite to the leaf, about two inches long, and ſuſtain one globular head of flowers at the top, of a purpliſh red colour. Seeds oblong, ſituated on the margin.

[Stems branched above and below, even. Leaves naked,

Digitized by Google

naked, ſeſſile and totally decurrent, foliation involuted and having the ſmell of oil of Lavender. Flowers ſolitary, terminating, ſubglobular, blue. Style ſtanding out. Peduncle on each branch ſingle, oppoſite to a leaf: and a one-flowered branch from the axil of the next leaf, below the peduncle. It is unuſual certainly, that the peduncle ſhould not ariſe from the axil of its leaf, but ſhould be oppoſite to a leaf, and that the next leaf (which has nothing in common with the peduncle) ſhould produce only a branch [r].

Common receptacle globular, within hollow, without chaffy; one chaff to each partial calyx, ovate, acuminate, villoſe: partial receptacle very narrow, dotted, ſmooth, naked. Seeds to the female flowers ſmall, ovate, of a brown-bay colour with whitiſh little briſtles ſcattered over them.—The fifteen chaffs to each of the partial florets, and the five-toothed female corollets, which Adanſon attributes to Sphæranthus, are not to be found in this ſpecies; perhaps therefore he means the *S. africanus*, concerning which Juſſieu doubts whether it belongs to this genus [s].

Native of the Eaſt Indies. Cultivated in 1709, by the Dutcheſs of Beaufort. It flowers from auguſt to december [t].

2. This differs from the preceding chiefly in having the peduncles round, without any decurrent wings [u]. This is marked by Linneus as annual, and the former as perennial.] According to Miller, they are both annual. He deſcribes this as riſing with an herbaceous winged ſtalk about ten inches high, with ovate-lanceolate, ſerrate, alternate leaves; the upper part of the ſtalk branching out into ſmall diviſions, terminated by peduncles, ſuſtaining three or four globular flowers of a pale yellow colour.

It grows naturally at Madras, and alſo at La Vera Cruz in New Spain, where it was diſcovered by Dr. Houſtoun. [Linneus ſays Africa and Aſia.

3. This is a much ſmaller plaſit than the firſt, with pinnate-ſinuate leaves. Peduncles curled with the decurrent wings, as in *S. indicus*.—Native of India [x]. But why then named *chinenſis?*

4. Stem herbaceous, a foot and half high, upright, round, ſmooth, white; with a few aſcending branches: appearing to be three-ſided, by the leaves running down them. Leaves blunt, waved, ſomewhat wrinkled, ſeſſile, alternate, lanuginoſe. Flowers white tinged with a little purple, in ſmall ſolitary heads, on ſhort peduncles.

Native of China and Cochinchina, among the corn and in gardens. They uſe it, chiefly externally as a cataplaſm to reſolve tumours in the breaſt; and the expreſſed juice in opthalmia: internally the decoction as a gargariſm in inflammation of the jaws.

S. amaranthoides of Burm. ind. 186. if not the ſame, differs little from this. S. chinenſis of Linneus would alſo ſeem to be the ſame, if it had not pinnatifid leaves, whereas in this they are quite entire [y].]

PROPAGATION AND CULTURE.

Sow the ſeeds in a hot-bed in the ſpring; and keep the plants in a ſtove or glaſs-caſe, giving them as much air as poſſible in warm weather.

[SPHÆRIA. A genus of Cryptogamia Fungi.

DESCRIPTION, &c.

This riſes with a ſhrubby ſtalk five or ſix feet high, ſending out many irregular branches, cloſely garniſhed with thin oval leaves ending in points, ſerrate and embracing. From the boſom of each leaf comes out one ſolitary white flower, which is cut at the top into five parts, and at firſt ſight has the appearance of a Jaſmine flower; but when cloſer viewed, the tube will be found curved, in the ſame manner with ringent flowers.

[The corolla like that of Jaſmine, the four ſtamens, the form of the nut, and the whole habit of the inflorescence,

Digitized by Google

floreſcence, ſeparate this plant from the Lantanas; with which it agrees in nothing but in the ſtructure of the hooked ſtigma. The eſſence of the genus conſiſts in the four anthers, not twin; the throat cloſed with hairs; the hooked ſtigma; and the nut divided by a partition into two equal hemiſpheres[z].

The upper leaves are alternate, and from the axils of theſe come out ſolitary flowers. The ſtamens are equal in length[a].

This ſhrub flowered and perfected its fruit in Ludwig's garden at Leipſic; and was found to have a five-parted calyx, which is permanent, and has awl ſhaped ſegments. The fruit an inſipid, globular, ſub-acuminate drupe, two-parted by a groove: the kernel globular and two-celled[b].

Native of the Cape of Good Hope. Cultivated in 1731, by Mr. Miller. It flowers from february to november[c].]

PROPAGATION AND CULTURE.

Flowers are not ſucceeded by ſeeds in England, but the plants are eaſily propagated by cuttings, which, if planted upon an old hot-bed any time in july, and covered with a bell or hand-glaſs, and ſhaded from the ſun, will put out roots in a month or five weeks; then they may be planted in pots, and placed in the ſhade till they have taken freſh root; after which they may be removed to a ſheltered ſituation, where they may remain till the froſts come on. This plant is not very tender, therefore may be preſerved in a good green-houſe in winter; but during that ſeaſon it muſt have a large ſhare of air in mild weather, otherwiſe it is apt to grow mouldy, and this will cauſe the tender branches to decay. In the ſummer ſeaſon it may be expoſed in the open air, with other green-houſe plants, in a ſheltered ſituation, where it will add to the variety; and although the flowers are ſmall, and are produced ſingly from between the leaves, ſo do not make any great appearance; yet as there is a ſucceſſion of theſe flowers moſt part of the year, and the leaves continue green throughout the year, it is worthy of a place in every collection of plants.

SPIGELIA. (*So named by Linneus, in memory of Adrian Spigelius, born at Bruſſels in* 1578; *profeſſor of anatomy and ſurgery at Padua: died* 1625. *Author of* Iſagoge in rem herbariam. Pat. 1606. qu. & Lugdb. 1633. 24°.)

Stem four-cornered, all the leaves oppoſite.

DESCRIPTIONS, &c.

1. This is an annual plant with a fibrous root, from which ariſes a ſtrong erect herbaceous ſtalk, a foot and half high, channelled, ſending out two ſide branches oppoſite near the bottom, and a little above the middle four acute-pointed leaves placed in form of a croſs; theſe, and alſo the principal ſtalk, have four ſmaller leaves near the top, placed round in the ſame manner as the others; and from theſe ariſe ſhort ſpikes of herbaceous flowers, ranged on one ſide of the foot-ſtalk; which are ſucceeded by roundiſh twin capſules containing ſmall ſeeds.

[Stem ſimple. Terminating leaves lanceolate, four; the reſt on the ſtem oppoſite in pairs. From each axil of the ſtem-leaves a ſingle branch, very like the ſtem, terminated, as in that, by four leaves placed croſſwiſe. Racemes terminating ſolitary on the ſtem and branches[d]. It riſes from a ſmall tapering root, well charged with fibres on all ſides, and ſhoots by a ſtraight ſmooth roundiſh hollow ſtalk, which ſeems to grow thicker as it riſes to the height of five, ſeven, nine or thirteen inches, its uſual growths; the main ſtem emits two, four or ſix lateral oppoſite branches, as it riſes, which like the parent ſtalk, are furniſhed with four oval pointed and almoſt equal leaves diſpoſed in the form of a croſs at the top: from the centre of theſe it throws out one, two or more ſpikes, which bear all their flowers and ſeed-veſſels on one ſide, and are commonly from half an inch to two or three inches in length[e].

Native of the Weſt Indies. Cultivated by Mr. Miller in 1759. It flowers in july[f].

This vegetable has been long in uſe among the Negroes and Indians, and takes its names (of Anthelmia, Anthelmenthia, and Worm-graſs,) from its peculiar efficacy in deſtroying worms; which I dare affirm, (ſays Dr. Browne) from a great number of ſucceſsful experiments, it does in ſo extraordinary a manner, that no other ſimple can be of equal efficacy in any other diſeaſe as this is in thoſe that proceed from theſe inſects, eſpecially when attended with a fever or convulſions.

Take of the plant, roots and all, either freſh or dry, two moderate handfuls, and boil them over a gentle fire in two quarts of water until one half of the liquid is conſumed; then ſtrain off the remainder, and add a little ſugar and lemon juice, to give it a more agreeable taſte, and to keep it from growing viſcid or ropy.

To a full-grown perſon give half a pint at the hour of reſt, and a proportionate quantity to all weaker and younger ſubjects. Repeat the doſe once in twenty-four hours for two or three days after. But as the largeneſs of this doſe may render its operation too violent, the following method is leſs hazardous, and as effectual.—Give about four ounces to a full grown perſon for the firſt doſe, and two or three ounces every ſix hours after, if its anodyne quality will permit; but to perſons of a weaker conſtitution it ſhould be repeated only every ten or twelve hours: this is to be continued for thirty-ſix or forty-eight hours, when the double doſe may be again repeated; and after this takes its full effect, it muſt be worked off with ſome gentle purgatives.

This medicine procures ſleep almoſt as certainly, and in an equal degree with Opium; but the eyes ſeem diſtended, and appear bright and ſparkling, as they generally do before the eruption of the ſmall-pox and meaſles, after the ſleepy effects are over. In a ſhort time after this firſt doſe is adminiſtered, the pulſe grows regular and begins to riſe; the fever cools; the convulſions, if any, abate; and the worms are

[d] Linn. ſpec. [e] Browne. [f] Hort. kew.

generally

Digitized by Google

generally discharged in great quantities, by the use of the subsequent purgatives, if not before; often above a hundred at a time: but when a few only come away, and those alive, which seldom is the case, the dose must be repeated, and this scarcely ever fails[g].]

2. This has a perennial fibrous root, from which arise two or three erect herbaceous stalks, seven or eight inches high; having three or four pairs of acute-pointed leaves, placed opposite, sitting pretty close to the stalk, smooth, entire, and having several veins diverging from the midrib. The stalk is terminated by a short spike of flowers, ranged on one side the foot-stalk. Calyx short, cut into five acute segments. The outside of the flower is of a bright red, and the inside of a deep orange colour.

[Stems simple, rugged, quadrangular, rigid, annual. Leaves opposite, sessile, ovate-lanceolate, quite entire, smooth, spreading. Spike solitary, with small opposite bractes. Calyx five-leaved; with awl-shaped, permanent leaflets. Corolla five-cornered above, gibbous at the throat, widening at the base: border five-parted; the parts lanceolate and revolute. Stamens shorter than the corolla: anthers sagittate, converging. Style cylindric, jointed below, the upper part deciduous. Stigma attenuated. Capsule roundish, twin: cells two-valved. Seeds angular, rugged[h].

Native of North America, in the warmer parts, as Virginia, Maryland, and Carolina, where it is called Indian Pink. It flowers here in july and august. Cultivated in 1694 by Bobart[i].

The accounts of the vermifuge virtues of Spigelia given by Drs. Linning and Garden refer to this species; and as the efficacy resides chiefly in the root, which in the preceding is small, this should seem to be preferable. Dr. Garden, in his first letter to Dr. Hope, about the year 1763, says, about forty years ago, the anthelmintic virtues of the root of this plant were discovered by the Indians; since which time it has been much used by physicians and planters. I never found it do much service, except when it proved gently purgative.

Previous to the use of it, I have lately given a vomit, when the circumstances of the case permitted it, and have found it to answer so well, that it should never be omitted. I have known half a dram of this root purge as briskly as the same quantity of rhubarb; but at other times it has produced no such effect, in larger quantities. It is in general safer to give it in large doses; for giddiness, dimness of sight and convulsions frequently result from small ones, whereas large ones only prove emetic or violently cathartic. To a child of two years of age, who had been taking ten grains of the root twice a day, without any other effect than making her dull and giddy, I prescribed twenty-two grains morning and evening, which purged her briskly, and brought away five large worms. After some months an increased dose had the same good effects. Of the root properly dried I give from twelve to sixty or seventy grains in substance. In infusion it may be given to the quantity of two, three or four drams twice a day.

In Dr. Garden's subsequent letters to Dr. Hope in the years 1764 and 1766, the efficacy of this root in worm cases is farther confirmed. In what he calls continued or remitting low worm fevers, he found its efficacy promoted by the addition of the root of Serpentaria virginiana[k].]

PROPAGATION AND CULTURE.

1. Sow the seeds in pots filled with soft loamy earth, in the autumn, and plunge them into the bark-bed, where they should remain till the spring, when they must be plunged into a fresh hot-bed. Afterwards plant them in separate pots, shading them till they have taken root; and then treat them in the same way as other tender annual plants from the same countries, keeping them constantly in the hot-bed under cover to perfect the seeds. They ripen in september, and should be sown soon after; for if they are kept out of the ground till spring, they frequently fail. But Mr. Miller was not able to raise any plants from English seeds.

2. This is not easily propagated in England, for the seeds do not ripen here, and the roots increase slowly; so that the plant is very uncommon in the English gardens at present. It delights in a moist soil, and must not be often transplanted.

[The scarcity of this plant, even now, is a proof, says Mr. Curtis, of the justness of Mr. Miller's observation; it is, in fact, very difficult of culture, and scarcely to be kept in this country but by frequent importation.

DESCRIPTIONS, *&c.*

This new genus is made up chiefly of thoſe ſpecies of *Bidens* and *Verbeſina* which do not properly belong to thoſe genera. They are inhabitants of the Eaſt or Weſt Indies.

1. Root perennial. Stems herbaceous, round, ſmooth, branched, procumbent and putting out round whitiſh fibres from the joints. Leaves numerous, narrow-lanceolate, acute, ſmooth on both ſides, gray on the under ſurface, ſeſſile, always oppoſite, three-nerved, the nerves united above the baſe, an inch and half long. Theſe leaves when chewed for ſome time, are very hot, like the root of *Pyrethrum* or Pellitory of Spain, and are uſed for the ſame purpoſes as that. Peduncles one-flowered, ſolitary, ſuberect together with their branchlet, long, ſubterminating, bearing a whitiſh flower, void of ſcent, variegated with black dots, which proceed from the anthers ſhedding their dark pollen over the corolla. After the flower is perfectly opened, from the ſide of the peduncle at the baſe, a new leafy ſtemlet ſprings forth, which in time produces its flower.

Native of America, about Carthagena, in ſandy fields; flowering from may to october [l].

2. Stem upright, round, brown, ſtiffiſh, rough with white ſcattered procumbent hairs. Branches oppoſite. Leaves oppoſite, petioled, without ſtipules, ovate, three-nerved, veined, naked, deeply ſerrate, opaque. Petioles ſlightly channelled, ſcarcely pubeſcent. Peduncles from the forkings of the ſtem, ſolitary, one-flowered, round, upright, naked, long. Flower together with the calyx ovate, yellow, without any ray. Corollets five-cleft. Calyx ſqueezed with four or five leaflets, the outer ones a little ſhorter [m].] It is an annual plant, with the ſtalks two feet high.

Native of Ceylon. [Cultivated in 1768, by Mr. Miller. It flowers in july [n].

3. Root annual, fibrous, whitiſh, exciting ſaliva, whence Murray's trivial name of *ſalivaria*. Stem herbaceous, upright, ſomewhat flexuoſe, very much branched, looſely panicled, round, ſomewhat rugged, green, a foot high. Branches like the ſtem, the lower alternate, the upper oppoſite, roughiſh with hairs, ſcarcely ſtriated. Leaves ſpreading, bluntiſh, attenuated at the baſe and running down along the petiole, ſerrulate-ciliate with ſmall ſtiffiſh hairs, and having the ſame ſort of hairs ſcattered over both ſurfaces, bright green, of the ſame colour on both ſides, flat, two inches long, and fifteen lines wide. Petioles channelled, margined above; the upper ones gradually ſhorter. Flowers terminating, ſolitary, erect, conical, obtuſe, white; on erect, ſtriated, ſubvilloſe peduncles, ſcarcely thicker at the top, higher than the plant, from twelve to fifteen lines long.

[l] Jacquin. [m] Linn. mant. [n] Hort. kew.

Native of Peru, whence it was ſent to the Paris garden by Dombey [o]. In 1783, it was introduced at Kew by Monſ. Thouin. It flowers in june and july [p].

The whole plant ſtimulates the tongue and palate, and produces ſaliva, like the *oleraceus* and its congeners.

Spilanthus is diſtinguiſhed from *Bidens*, by having the ſcales of the calyx in a regular erect double row: the ſeeds vertical, flat, margined, ciliate, not awned but having two naked briſtles at the tip: the receptacle fuſiform, with the chaffs keeled and much compreſſed [q].

4. This is ſo like the ſecond ſpecies as ſcarcely to be diſtinguiſhed from it; but it is more branched and many-flowered, with moſt of the florets in the diſk four-cleft, a few only that are five-cleft mixed along with them, but it differs chiefly in having a ſmall five-flowered ray, which the other had not; but that might be owing to the defect of climate [r]:] and Mr. Miller ſays that the *Pſeudo-Acmella* has ſhort rays of female flowers.

The ſtalks riſe two feet high. The peduncles are very long, and ſupport one yellow flower, with very ſhort rays. There is a ſucceſſion of flowers from july till the froſt puts a ſtop to them, when the plant decays.

Native of Ceylon. Cultivated in 1768, by Mr. Miller [s].

This plant is reputed to be a ſpecific in the ſtone, in the Eaſt Indies; and there is a long account of it in the third volume of Ray's hiſtory, communicated by Profeſſor Hotton from Leyden, in may 1700.

5. Stem herbaceous, three feet high, round; with a creeping root. Leaves unequally ſerrate, ſmooth on both ſides, nerveleſs, oppoſite, juicy, bright green. Flowers whitiſh-blue: calyx-leaves equal, obtuſe. Receptacle convex, naked. Seeds three-awned.

Abecedaria of Rumphius ſcarcely differs in form from this plant, if we except the one-flowered lateral peduncles: but he makes no mention of the uſe of that in dyeing. In this circumſtance, and in ſome marks this ſpecies agrees with *Serratula tinctoria* of Linneus, but the leaves are different, and the awns of the ſeed-down refer it to this genus.

It is cultivated for dyeing both in China and Cochinchina. The leaves bruiſed yield a moſt excellent blue colour, and a green prepared by a method more eaſy than from Indigo, and by no means inferior in brightneſs [t].

6. This is an annual plant, native of Jamaica [u].

7. Seeds awnleſs. Receptacle conical. Native of South America [x].

8. Stems ſhrubby, round, branched, procumbent. Leaves attenuated at the baſe, very ſmooth, crenate-toothed, acuminate, ſubſeſſile, oppoſite, an inch and half long, having a ſalt taſte, and in ſome degree biting. Peduncles and flowers very like thoſe of *urens*.

Native of America. Found by Jacquin at the Havanna; where it flowers in december and january [y].

9. Stems procumbent, a foot long, round, ſomewhat rugged. Leaves oppoſite, blunt. Flowers ſolitary, on long peduncles, yellow [z]. Receptacle cylindrical, very long, covered all over with herbaceous membranaceous chaffs, coloured at the tip, in part embracing the ſeeds. Seeds ſmall, ovate-oblong, compreſſed, with little white briſtles ſcattered over it, brown, with whitiſh ciliate margins. Seed-down ſetaceous-awned: with two rays, ſhorter than half the ſeed, a little matter unequal, flexile, ſmooth [a].

Native of the Eaſt Indies. Introduced in 1770, by Monſ. Richard. It is annual, and flowers from july to november [b].]

PROPAGATION AND CULTURE.

Sow the ſeeds upon a moderate hot-bed in the ſpring, and when the plants are fit to remove, tranſplant them on to a freſh hot-bed, ſhading them till they have taken new root, and then treating them as

DESCRIPTIONS, *&c.*

1. Root annual. Leaves ſagittate. Stem hollow, branching, herbaceous, about two feet high. The male flowers are herbaceous, in long ſpikes; they abound in pollen, which, when ripe, flies out when the plants are ſhaken, and ſpreads all round; after which the plants ſoon decay. The female flowers, which are on a ſeparate plant, ſit in cluſters cloſe to the ſtalks at every joint; they are ſmall, herbaceous, and are ſucceeded by roundiſh ſeeds, which (in variety α) are armed with ſhort acute ſpines.

There are two or three varieties of this, which differ in the ſize and ſhape of the leaves; and the more or leſs pricklineſs of the ſeeds.

β. Smooth or round Spinach has ovate thick leaves, not angular at their baſe; both ſtalks and leaves are much more fleſhy and ſucculent; and the ſeeds are ſmooth without any ſpines. Of this alſo there are two or three varieties, differing in the ſhape, thickneſs and ſize of their leaves.

[The ſeed has no proper pericarp; but the calyx gradually hardens and cloſes over the ſeed; this is ſometimes unarmed; or it is terminated by two, three or four channelled ſpines ſpreading out horizontally; this covering protects the ſeed and does not drop it. The ſeed is ſubglobular, acuminate at the baſe, where it is faſtened to the bottom of the calyx[c].

The native place of growth is unknown. There is no mention of this plant among the ancients; but with the moderns the uſe of Spinach has been of long date. The Arabian phyſicians ſpeak of it, and it has been known time out of mind in Spain, inſomuch that it has been called *Hiſpanum olus.* Perhaps the Spaniards might have it from the Saracens: but this I propoſe as matter of conjecture, for thoſe to enquire into who have more leiſure. It has been cultivated in England, as far back as we have any records of ſuch things: being mentioned by Turner in 1568[d].

The etymology of this well-known pot-herb is involved in much obſcurity. Latin names ending in *aca*, as Verbenaca, Portulaca; or in *acia*, as Spinacia; are deduced from ſomething to which they bear a reſemblance, as Verbena, Portula, Spina: hence our Engliſh names Smallach, Spinach, now commonly ſpelt Smallage, Spinage.

Much ſtreſs has been laid by the opponents of the doctrines of the ſexes in vegetables, upon plants having been produced from the ſeeds of female Spinage, from which all male plants have been carefully ſeparated. But they were not aware that it is by no means uncommon in this and other dioecious vegetables, to have ſome hermaphrodite flowers mixed among the females[e].

2. Stem higher, ſmooth and even. Leaves deltoid-ovate, ſometimes ſinuate, obtuſe, petioled. Fruits axillary, three or more, each on its peduncle, the length of its fruit, ovate or obovate, obtuſe, ſomewhat keeled on each ſide, even, very blunt.—Native of Siberia[f].]

PROPAGATION AND CULTURE.

Prickly Spinach was formerly more cultivated in the Engliſh gardens than at preſent, becauſe it is much hardier, ſo not in much danger from cold, therefore was generally cultivated for uſe in winter.

The ſeeds ſhould be ſown upon an open ſpot of ground the beginning of auguſt, obſerving, if poſſible, to do it when there is an appearance of rain; for if the ſeaſon ſhould prove dry for a long time after the ſeed is ſown, the plants will not come up regularly; part of them may come up ſoon, and a great part of them may remain till rain falls before they come up; and if that ſhould not happen in a little time after, many times there will not be half a crop. When the Spinach is come up, and the plants have four leaves, the ground ſhould be hoed to deſtroy the weeds, and alſo to cut up the plants where they are too cloſe, leaving the remaining plants about three or four inches aſunder; but this ſhould always be done in dry weather, that the weeds may be deſtroyed ſoon after they are cut.

About a month or five weeks after the firſt hoeing, the weeds will begin to grow again; therefore the ground ſhould be then hoed the ſecond time, obſerving, as before, to do it in dry weather. But if the ſeaſon ſhould prove moiſt, it will be proper to gather the weeds up after they are cut, and carry them off the ground; for if the Spinach is not cleaned from weeds before winter, they will grow up and ſtifle it ſo much, that in wet weather the Spinach will rot away.

In october the Spinach will be fit for uſe, when you ſhould only crop off the largeſt outer leaves, leaving thoſe in the centre of the plants to grow bigger; and thus you may continue cropping it all the winter and

[c] Gærtner. [d] Hort. kew.
[e] Thunb. præf. ad flor. japon. xxi. [f] Lin. ſpec.

ſpring,

Digitized by Google

ſpring, until the young Spinach ſowed in the ſpring is large enough for uſe, which is commonly in april; at which time the ſpring advancing, the Winter Spinach will run up to ſeed; ſo that it ſhould be all cut up, leaving only a ſmall parcel to produce ſeeds if wanted.

But if the ground in which this Winter Spinach is ſown, be planted with early Cabbages, it is not proper to let any of the Spinach remain there for ſeed; therefore it ſhould be cleared off as ſoon as ever the Spring Spinach is fit for uſe, that the Cabbages may be earthed up and laid clear, which is of great ſervice to them; wherefore you ſhould ſow a ſmall ſpot of ground with this ſort of Spinach, on purpoſe to ſtand for ſeed, where there ſhould be no other plants among it.

Smooth-ſeeded or round-leaved Spinach is ſown in the ſpring upon an open ſpot of ground ſeparate, or elſe mixed with Radiſh-ſeed, as is the common practice of the London gardeners, who always endeavour to have as many crops from their land in a ſeaſon as poſſible; but where land is cheap in the country, it will be the better method to ſow it alone; and when the plants are come up, the ground ſhould be hoed to deſtroy the weeds, and cut out the plants where they are too cloſe, leaving the remaining about three inches aſunder; and when they are grown ſo large as to meet, you may then cut out a part of it for uſe, thinning the plants that they may have room to ſpread; and this thinning may be twice performed, as there is occaſion for the herb, at the laſt of which the roots ſhould be left eight or ten inches aſunder; and if then you hoe the ground over again to deſtroy the weeds, it will be of great ſervice to the Spinach; for if the land is good upon which it is ſown, the ſort with broad thick leaves, commonly called Plantain Spinach, will with this management many times produce leaves as large as the broad-leaved Dock, and be extremely fine.

But in order to have a ſucceſſion of Spinach through the ſeaſon, it will be proper to ſow the ſeed at three or four different times in the ſpring; the firſt in january, which muſt be on a dry ſoil; the ſecond the beginning of february, upon a moiſter ſoil; the third the beginning of march, which ſhould be on a moiſt ſoil; and the fourth the beginning of april; but theſe late ſowings ſhould be hoed out thinner at the firſt time than either of the former, for there will be no neceſſity to leave it for cutting out thin for uſe, becauſe the former ſowings will be ſufficient to ſupply the table till theſe are full grown; beſides, by leaving it thin at firſt, it will not be apt to run up to ſeed ſo ſoon as it would if the plants were cloſe.

Theſe ſowings here mentioned are ſuch as are practiſed by the kitchen-gardeners near London; but as this herb is much uſed in ſoups, &c. for great tables, there ſhould be ſome ſeeds ſown every three weeks, during the ſummer ſeaſon, to ſupply the kitchen; but theſe late ſowings ſhould be on moiſt ſtrong ground, otherwiſe, if the ſeaſon proves hot and dry, the Spinach will run to ſeed before the plants obtain ſtrength, eſpecially if the plants do not ſtand thin.

In order to ſave ſeeds of either of theſe kinds, you ſhould ſow an open rich ſpot of ground, with the ſort you intend in february, after the danger of being injured by froſt is over; and when the plants are come up, they ſhould be hoed out to ſix or eight inches diſtance, obſerving to cut down the weeds at the ſame time; and when the plants have grown about three weeks or a month longer, they ſhould be hoed a ſecond time, when they ſhould be left twelve or fourteen inches aſunder at leaſt, for when they have ſhot out their ſide branches they will ſufficiently ſpread over the ground.

You muſt alſo obſerve to keep them clear from weeds, which, if ſuffered to grow amongſt the Spinach, will cauſe it to run up weak, and greatly injure it. When the plants have run up to flower, you will eaſily perceive two ſorts amongſt them, viz. male and female. The male will produce ſpikes of ſtamineous flowers, which contain the farina, and are abſolutely neceſſary to impregnate the embryos of the female plants, in order to render the ſeeds prolific. Theſe male plants are, by the gardeners, commonly called She Spinach, and are often by the ignorant pulled up as ſoon as they can be diſtinguiſhed from the female, in order, as they pretend, to give room for the ſeed-bearing to ſpread; but, from ſeveral experiments which I have made on theſe plants, I find wherever the male plants are entirely removed before the farina is ſhed over the female plants, the ſeed will not grow which they produce, ſo that it is abſolutely neceſſary to leave a few of them in every part of the ſpot, though there may be a great many drawn out where they are too thick, for a ſmall quantity of male plants (if rightly ſituated) will be ſufficient to impregnate a great number of female, the farina when ripe, ſpreading to a conſiderable diſtance, when the plants are ſhaken by the wind.

When the ſeeds are ripe (which may be known by their changing their colour, and beginning to ſhatter, the plants ſhould be drawn up, and ſpread abroad for a few days to dry, obſerving to turn them every other day, that the ſeeds on both ſides may dry equally; you muſt alſo guard the ſeeds from birds, otherwiſe they will devour them. When dry, the ſeeds ſhould be threſhed out, cleaned from the dirt, and laid up for uſe where mice cannot come to them, for they are extremely fond of this ſeed.

DESCRIPTION, *&c.*

Culms very large, as thick as the finger, glaucous, as is the whole plant, jointed, with heaps of leaves at every joint, even, not hollow but full. Leaves graſſy, convolute; recurved-ſpreading, rigid, ſpiny at the end: ſheaths widened, ſtriated, with a woolly ligule. Bundles three or four, terminating, compoſed of ſeveral ſmaller bundles; the latter of a few lanceolate ſhorter leaflets without ſheaths; among theſe are the ſpikes, moſt commonly three. Each ſpike near a finger's length; with a three-ſided rachis ending in a ſpine and five alternate lateral ſeſſile remote flowers. Theſe are ovate-oblong, with the ſide, not the belly, turned towards the rachis, as in the leaf. Glume two-valved: valves ovate, lanceolate, ſtriated, acute.

Native of the Eaſt Indies, China and Cochinchina, on ſandy coaſts [s].

Claſſ. 12. 4. Icoſandria Pentagynia.
Nat. order of *Pomaceæ.* *Roſaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-cleft, flat at the baſe, with acute ſegments; permanent.
COR. *Petals* five, inſerted into the calyx, oblong-rounded.
STAM. *Filaments* more than twenty, filiform, ſhorter than the corolla, inſerted into the calyx. *Anthers* roundiſh.
PIST. *Germs* five or more. *Styles* as many, filiform, length of the ſtamens. *Stigmas* headed.
PER. *Capſules* oblong, acuminate, compreſſed, two-valved.
SEEDS few, acuminate, ſmall, faſtened to the internal ſuture.
OBS. Filipendula, Tourn. *has numerous capſules in a ring.*
Ulmaria, Tourn. *has numerous capſules contorted as in Helicteres.*
Aruncus *differs from the reſt in being dioecious.*
S. opulifolia *is trigynous.*

ESSENTIAL CHARACTER.

Cal. five-cleft. *Pet.* five. *Capſ.* many-ſeeded.

DESCRIPTIONS, &c.

[1. Shrubby with round branches. Leaves alternate, bluntiſh, mucronate, very even. Racemes terminating, ſolitary, erect, compoſed of alternate, erect, racemelets, ſupported by a ſmall bracte. Flowers longer than the pedicel, white, alternate. Stamens longer than the corollas[h].

Stems wand-like, numerous, ſtraight, ſtout, the thickneſs of a finger, little branched, covered with a ſmooth bark, of a glaucous-teſtaceous colour, very tough, and at the end ſomewhat herbaceous. Leaves on the older ſtems in alternate cluſters; on the younger branches ſingly alternate, oblong, ſmooth, quite entire, ſoft, narrowed at the baſe into a ſort of winged petiole, having a toothlet or very ſmall point at the end, emerging from the nerve. Racemes compoſed of

[h] Linn. mant.

partial

Digitized by Google

partial ones, commonly about twelve; when fruiting, ſubfaſtigiate. Flowers white, nearly of the ſame ſize as in *chamædrifolia*. Calyx flattiſh, acutely five-cleft, ſmooth. Petals ovate. Stamens about thirty, a little longer than the petals, with ovate anthers of a pale yellow colour. Germs commonly four or five. Capſules for the moſt part four, (five or ſix, immerſed in the woolly bottom of the calyx, ſmall, oblong, *Gærtn.*) biggiſh, teſtaceous, hard, ſhaped like ſilicles, erect; when freſh, ſomewhat clammy, with a fragrant roſy ſmell. Seeds uſually two in each capſule, very large, linear-lanceolate, teſtaceous: (four, pendulous, oblong, ſlightly incurved, acuminate, angular, bay, *Gærtner.*)

Native of Siberia, in vallies at the foot of the loftier Altaic mountains, which are covered with ſnow. Flowering in the ſpring, ripening its capſules at the beginning of auguſt, and then flowering again from the lateral branches. The ſhoots being tough, very ſtraight, and of a proper ſize, are uſed by the Coſacks for ramrods. The leaves being gently and pleaſantly aſtringent, may ſerve as a ſuccedaneum for tea[i].

Introduced in 1774, by Daniel Charles Solander, L. L. D. It flowers from april to june[k].

2. This ſhrub is about four feet high, with rod-like ſtems, ſmooth; the branches yellow. Leaves alternate, ſubſeſſile, broad-lanceolate, unequally ſerrate, ſmooth on both ſides. Racemes terminating, ſolitary, erect, decompound, obtuſe, many-flowered; with linear, ſolitary bractes. Corollas of a roſe-red, paler when expanded[l].]

Miller deſcribes the ſhrub as it is commonly cultivated in our nurſeries under the name of *Spiræa Frutex*. Stalks very taper, and rough towards the top, and covered with a reddiſh bark. Leaves about three inches long, and an inch broad in the middle, bluntly ſerrate, and of a bright green colour. In rich moiſt ground the ſtalks will riſe five or ſix feet high, but in moderate land from three to four; for their whole height is one year's growth from the root. They are terminated by ſpikes of pale red or fleſh-coloured flowers: the lower part of the ſpike is branched out into ſmaller, but the upper part is cloſe and obtuſe. Some of the ſtamens ſtand out much beyond the petals, but others are not ſo long; they are terminated by brown headed anthers. The capſules are pointed, but rarely come to perfection in England. This ſhrub flowers in june and july; and in moiſt ſeaſons there are frequently young ſhoots from the root which flower in autumn.

[Pallas deſcribes it thus as found wild in Siberia. From a prolific root this ſhrub is widely luxuriant, with numerous upright ſhoots, little branched, rod-like, clothed with a greeniſh bark, and a browniſh fiſſile deciduous epidermis. Branches herbaceous at the end, round, ſtriated, yellowiſh, hairy, leafed alternately, flowering at the top. Leaves petioled, broad-lanceolate, pubeſcent, in the larger variety very ſharp, deeply and ſharply ſerrate; the ſerratures double: in the ſmaller variety they are blunter, ſimply ſerrate only here and there, more hoary and drier. Racemes in the larger compound and very handſome; in the low one ſimple, very ſhort, ſometimes a little compound, with one or two branchlets having three or four flowers on each. Bractes to the partial racemes lanceolate, together with the peduncles pubeſcent. The flowers have a little ſcent, before they open are of a very fine roſe colour, but afterwards of a pale fleſh-colour. Calyx minute, green, ſcarcely pubeſcent. Petals biggiſh, oval. Stamens more than twenty, much longer than the petals, pale; with yellow anthers. Capſules erect, biggiſh, teſtaceous, very ſeldom ripening in gardens.

By the banks of rivers it is often a fathom high, with longer leaves and large handſome racemes of flowers, as it appears in gardens: but on the rocky ſides of mountains it is ſmaller and more branched, with ſhorter leaves, and a very ſhort ſimple raceme. The latter of theſe Willdenow has diſtinguiſhed as a variety, under the name of *alpeſtris*.

It begins from the river Ob, and thence becomes gradually more abundant about the Jeniſea, and in the country beyond the lake Baikal.

Pallas can ſcarcely believe it to be wild in Sileſia. Nor can I credit its being indigenous of England, though it occurs ſometimes in moiſt hedges in Weſtmoreland, in many places on the borders of Winandermere; and alſo between Poolbridge and Colthouſe near Hawkſhead, Cumberland; and in a wood at Hafod, Cardiganſhire.]

γ. The ſtalk of the panicled variety is covered with a bright brown bark, and riſes five or ſix feet high, ſending out many ſlender horizontal branches on every ſide. The leaves are of a thin conſiſtence, and a bright colour on both ſides, ſharply ſerrate, and upon ſhort petioles. The flowers are diſpoſed in panicles at the end of the branches: the petals are ſmall, roundiſh and white; filaments many and ſhort, terminated by roundiſh red anthers. It flowers in july and auguſt, but rarely produces good ſeeds in England. It grows naturally in North America, whence Mr. Miller received it. [This variety, which is deſcribed and figured in Mr. Miller's plates, and deſcribed in the ſeventh edition of his dictionary, as a diſtinct ſpecies, is wholly omitted in the eighth.

δ. The broad-leaved variety is alſo a native of North America.

It appears from Rea's Flora, that the common Spiræa Frutex was cultivated here in 1665[m].

3. Branches and branchlets alternate, roundiſh, villoſe, purpliſh, erect. Leaves alternate, elliptic, unequally ſerrate, ſerratures remote and not glandular; the lower leaves villoſe, eſpecially on the nerves; the upper green, glaucous beneath, nerved, erect, an inch and half long. Petioles a line in length, ſemicylindric, with a ſmooth red calloſity on each ſide of the baſe without. Flowers red. Peduncles and pedicels villoſe.—It differs from *tomentoſa* in having villoſe, not tomentoſe leaves, and the flowers in panicles:—from *ſalicifolia*, in having the leaves manifeſtly petioled, elliptic, ſharper and longer, with the ſerratures remote; the panicle faſtigiate, not ſpiked; the under ſurface of the leaves, the ſtem, and peduncles villoſe.

Native of Japan, in the iſland Nipon; flowering in june[n].

4. This differs from the *ſalicifolia* in having the leaves more deeply and unequally ſerrate, very tomentoſe beneath; the terminating compound raceme cloſer and longer; the flowers of a deeper red, and eight times ſmaller; the fruits villoſe[o].]

The ſtalks are ſlender, and branch out near the ground; they have a purple bark covered with a gray mealy down. Leaves ſmaller than thoſe of *ſalicifolia*, downy and veined on their under ſide, but of a bright green above. Branches terminated by a thick raceme of flowers, branched towards the bottom into ſmall ſpikes. Flowers very ſmall, of a beautiful red colour, appearing in july, [auguſt and ſeptember.

Native of Pennſylvania. Introduced in 1736, by Peter Collinſon, Eſq.[p]

5. Branches ſtriated, erect, with ſhort branchlets. Leaves alternate, petioled, ſilky-tomentoſe on both ſides. Racemes longer than the branchlets. Flowers very ſmall, with villoſe germs.

Native of New Granada, where it was found by Mutis[q].

6. Shoots a cubit and half or two cubits (a yard) high. Theſe and the older branches are of a teſtaceous colour, with a browniſh epidermis, cloven longitudinally and deciduous. Leaves commonly from three to five in a bundle, or elſe alternate, very much narrowed at the baſe, ſeſſile, very finely ſerrulate at the edge or elſe entire. Corymbs on the ſhoots of the year, (which are ſhort and leafy) ſubglobular, diſpoſed all one way, as in *crenata*, but leſs abundant, and on more ſlender and longer peduncles. Flowers a little larger, with ſmooth calyxes. Capſules oblong, compreſſed, from erect parallel, gray.

This ſeems to be a middle ſpecies between *crenata* and *hypericifolia*. It differs from the former in its

place

Digitized by Google

place of growth, time of flowering, leaves which are not three-nerved, but very ſmooth, tender, attenuated towards the baſe but not petioled; in the outer ſkin of the ſhoots falling off; in the peduncles being more ſlender and longer; and the capſules being larger, and from upright parallel. It differs from the latter, in having the leaves acute and nerveleſs, not rounded and three-nerved; the flowers ſmaller, in many-flowered corymbs, not in ſeſſile few flowered umbels.

Native of eaſtern Siberia, eſpecially beyond the lake Baikal, and about the lake itſelf, flowering in june [x].]

7. This riſes with ſeveral ſlender ſhrubby ſtalks five or ſix feet high, covered with a dark-brown bark, ſending out ſmall ſide branches the whole length. Leaves ſmall, wedge-ſhaped, having many punctures on their ſurface, as in thoſe of St. John's-wort. Flowers in ſmall ſeſſile umbels, each on a long ſlender pedicel, and white. They appear in may and june, and as the flowers are produced almoſt the whole length of the branches, this ſhrub makes a good appearance during the time of flowering.

[It was cultivated here in 1640, according to Parkinſon [t]; who ſays that it came from the north-weſt parts of America. Miller ſays it came originally from Canada, and that country has been generally taken for its native place of growth. Yet Dr. Smith informs us that there is no ſpecimen of this ſhrub among the North American plants which Kalm gave to Linneus, and that it is to all appearance perfectly wild in Italy, where Dr. Smith found all the hedges full of it in flower, on the 28th of april, between Terni and Foligno. He adds, that its common Engliſh name of *Italian May*, ſeems to confirm the opinion of its being a native of Italy [y].—I did not know that ſuch is its common name in Engliſh; but ſurely it is a better appellation than that barbarous one of *Hypericum Frutex*, by which it is generally known among the nurſerymen.

8. Shoots abundant, ſeldom two ells high, the thickneſs of the finger, wand-like, branched. Wood brittle. Bark of the ſhoots yellowiſh-brown, with prominent dots ſcattered over it. Branches alternate, commonly angular, with a teſtaceous bark ſomewhat ſtriated, and in the younger branches covered with a tender aſh-coloured epidermis, which falls off; the annual ſhoots are grooved and pubeſcent. Leaves alternate, ſoftiſh, pubeſcent with proſtrate hairs, quite entire at the baſe, but commonly gaſh-ſerrate from the middle to the end, where they are ſharp. Corymbs at the top of the ſtems frequent, many-flowered, terminating the annual alternate ſhoots: in gardens and in moiſt ſhady places theſe corymbs are more elongated; but in a ruder ſoil moſt of the peduncles are cluſtered at the top like an umbel. Flowers biggiſh, white, having a weak viroſe ſmell, and fugacious. Stamens leſs than twenty. Capſules five, gray, erect, parallel, acute, mucronate outwardly with the ſtyle, inwardly opening longitudinally. Seeds like ſawduſt, gray and very ſmall.

This ſpecies varies very much, eſpecially with larger or ſmaller leaves, more or leſs cut, but more commonly quite entire and ovate-acute [z].

Native of Siberia, Hungary, Japan, and China about Canton.

On the rocks of Dauria, the leaves are very ſmall and very pubeſcent, inſomuch that they are almoſt tomentoſe; the flowers alſo are much ſmaller. At Kamtſchatka the leaves are ſomewhat tomentoſe [x].

The *chamædrifolia* of Jacquin is the next ſpecies, and the ſame with the *betulifolia* of Pallas.—According to Willdenow, the *cantonienſis* of Loureiro is this ſpecies.

In Kamtſchatka the leaves are uſed as a ſuccedaneum for tea, being ſlightly aſtringent. When the ſhoots are ſtraight, they make tobacco-pipes of them. This ſhrub makes beautiful hedges, being entirely covered with flowers in june. The capſules ripen in auguſt; but it does not readily grow from ſeed, and it does not throw out ſuckers ſo freely as ſome of the ſpecies [y].

[x] Pallas. [t] Hort. kew. [y] Tour. vol. 2. 304. [z] Pallas. [x] Idem. [y] Idem.

9. This is very different from the preceding: having ovate-lanceolate leaves groſsly double-toothed; not obovate, gaſhed only at the end, as in that: it has alſo larger flowers, and a higher ſtem [z].

It was imperfectly known to Pallas, only from dried ſpecimens among Steller's plants. The ſpecimen which Jacquin ſent him from Carniola, had the branches more ſharply angular than the Siberian *chamædrifolia*; the leaves larger, ſmoother, ſerrate, but ſcarcely gaſhed; the flowers much bigger; and the ſhrub in general ſtouter [a].

10. Stems ſeveral, ſcarcely two ells high, very much branched from the bottom. Branches rod-like, round, with a teſtaceous bark cloven longitudinally. Leaves on the younger branches and annual ſhoots alternate, attended with ſmaller ones in little bundles, hoary or glaucous, three-nerved, hardiſh, varying in form and ſize; on the luxuriant ſhoots or branches ſometimes ovate-acute, widiſh, ſerrulate from the tip beyond the middle; but commonly oblong, bluntiſh, crenulate or ſerrulate towards the tip, or more commonly quite entire. Corymbs at the ends of the annual twigs, very abundant, diſpoſed along the branches on one ſide, in hemiſpherical cluſters. Flowers ſmalliſh, white, odorous. Calyx bell-ſhaped, together with the peduncle ſomewhat pubeſcent: petals oval: ſtamens fewer than twenty, longer than the petals; with pale anthers. Capſules very ſhort, conical-mucronate, placed in a ſtar, calycled with the withered calyx, of a duſky teſtaceous colour [b].

Thunberg thus deſcribes it as found in Japan.—Stem ſhrubby, looſe, ſmooth in all its parts. Branches round. Branchlets filiform, alternate, brown, from upright ſpreading, looſe, capillary at the end, rod-like, a foot long, frequent, ſometimes ſubdivided. Leaves alternate, petioled, lanceolate, entire or ſerrate at the tip, frequent, erect, half an inch long. Flowers on the branchlets in umbels, two or three from each bud. Umbel ſimple, ſeſſile. Peduncles capillary, erect, one-flowered, the length of the internodes. The buds conſiſt of about ſeventeen leaflets, of which the twelve outer are imbricate, ovate, acute, purple; the five inner are equal, ovate, acute, green; for the moſt part incloſing three flowers. Calyx greeniſh purple. Petals white, ovate, emarginate, a line in length. Filaments twenty, the length of the calyx. Styles ſhorter than the filaments. Capſules five. There is a variety, with ovate wider leaves, and double flowers.

Willdenow thinks that the Spaniſh plant is different from this. It differs from *chamædrifolia*, with which it has been commonly confounded, in having the leaves ſerrate at the tip, three-nerved, not gaſhed at the end and veined; the corymbs more cluſtered, and in a ſort of head, and the flowers a little ſmaller.]

Mr. Miller ſays, that the whole appearance of the ſhrub from Spain is ſo like *hypericifolia*, as not to be diſtinguiſhed at a ſmall diſtance; the only difference being, that the leaves of this are broader at the point, where they have two or three indentures.

[Native of Spain, Ruſſia and Japan. Pallas ſays it is the only ſhrubby ſpecies of Spiræa, which is indigenous of European Ruſſia: and that it is ſo aſtringent as to be capable of tanning leather. It flowers about the middle of may, after leafing, and the fruit is ripe in auguſt.—With us it flowers in april and may; and it was cultivated by Mr. Miller in 1739 [c].

11. Stems numerous, ſcarcely thicker than a ſwan's quill, very much branched, upright, with a gray bark more or leſs pale, and ſomewhat angular with ſharp ſtreaks running down from the branches. Branches and branchlets alternate, thoſe of the laſt year very ſmooth, and yellow, leafy and terminated by an umbel. Leaves alternate, on very ſhort petioles, ſmooth, glaucous, wide-ovate, retuſe, gaſh-trilobate. They vary, even in the garden, with fewer or more frequent gaſhes, with the teeth or lobes obtuſe or acute, in breadth, &c. Umbels very frequent at the ends of the annual branches; peduncles often more than thirty, beſides a few axillary ones ſcattered below the umbel. Flowers

[z] Willdenow. [a] Pallas. [b] Idem. [c] Hort. kew.

Digitized by Google

middle-ſized, white: the five ſegments of the calyx ſhort and acute: the petals orbicular and emarginate: the ſtamens ſhorter than the petals and not very numerous. The five capſules gray, conical, ſpreading in form of a ſtar, mucronate with the ſtyle, calycled with the margined receptacle.

This elegant ſhrub is a native of Siberia, and is not ſeen till we arrive at the Altaic chain of mountains; thence it continues eaſtward to the Jeniſea and the lake Baical; being ſcarcely ever more than two feet high, even in the academical garden at Peterſburgh; on the Altaic rocks it is yet more dwarf. It multiplies very little by the root[d].

12. Stature of *crenata*, between which and *triloba* this ſeems to be a middle ſpecies. Branches ſtraight, ſtiffer, of a yellowiſh teſtaceous colour, ſcarioſe with the longitudinally cloven and deciduous epidermis. Leaves ſcattered alternately, here and there collected into little heaps, ſmooth, glaucous, ovate-wedgeform, produced into a longiſh petiole, very finely three-nerved; the lower ones almoſt entire, often oblong, moſt of them wider at the end, three-lobed-gaſhed, with the lobes blunt. At the ends of the branchlets and ſhoots are ſmall alternate ſeſſile umbels, containing from four to twelve flowers, accompanied by ſmall oblong leaves, ſometimes lobed. Hence they ſeem as it were racemed with flowers in bundles. Flowers white, ſcarcely larger than in *crenata*, with ſtamens more abundant and longer than in *triloba*. Capſules five, thickiſh, conical, of a yellow gray colour, mucronate with a ſetaceous ſtyle[e].

Willdenow remarks, that it has the habit of *hypericifolia*, but that the leaves are very different.

This elegant ſpecies is a native of Dauria, eſpecially in the tranſalpine parts, along with the *chamædrifolia* and *alpina*. It flowers earlier than the firſt of theſe.]

13. This riſes with many ſhrubby branching ſtalks, eight or ten feet high in good ground, but generally five or ſix; they are covered with a looſe brown bark which falls off. Leaves about the ſize and ſhape of thoſe of the common Currant buſh, ending in acute points, and ſerrate on their edges. The flowers are produced in roundiſh bunches at the end of the branches; they are white with ſome ſpots of a pale red.

[Linneus remarks, that this has only three ſtyles. Gærtner deſcribes it as having three or four capſules, which are ſeparate, ovate, acuminate at both ends, ſubmembranaceous, angular inwardly. Seeds two or three, ovate, narrowed and compreſſed a little towards the navel, bay-ſtraw-coloured, very ſmooth and ſhining, faſtened to the inner ſuture of the valves, and pendulous.

Native of Canada and Virginia. Cultivated in 1713 by Biſhop Compton[f].] It is commonly known in the nurſeries by the name of *Virginian Gelder Roſe*.

14. This riſes with ſhrubby ſtalks like the ſecond, but ſends out horizontal branches, which are ſlender, and covered with a brown bark. Leaves of a thin texture, and a bright green colour on both ſides, ſlightly and acutely ſerrate. Flowers in terminating panicles, ſmall and white. Stamens a little longer than the petals, with large, browniſh, round anthers.

[This ſhrub is often more than a fathom in height, very much branched from the bottom, and throwing out abundance of ſuckers from the root. Trunk round, the thickneſs of the wriſt next the root, covered with a browniſh aſh-coloured bark, having frequent warts on it; on the branches it is more of a gray aſh-colour with fewer warts. Wood brittle, hollow within with a ſoft ferruginous pith. Branches alternate, patulous, round, with herbaceous tops that decay every year. The twigs, petioles and peduncles have hairs thinly ſcattered over them which are elegantly ſtarred at the top; on the ſtipules and nerves of the leaves beneath there are alſo theſe ſtellate hairs, but the ſtar is almoſt ſeſſile; on the leaves they are very much ſcattered. Stipules at the baſe of the petioles large, lanceolate, erect, peculiar to this among the ſhrubby ſpecies. Leaves unequally pinnate, with the petioles often red, round, grooved above: leaflets ſoft, often ten pairs or more, lanceolate-acuminate, very elegantly doubly-ſerrate, grooved along the nerves; the end-leaflet often confluent with the next pair, and three-lobed.

Panicles of flowers terminating, on a flouriſhing ſhrub very abundant, a ſpan in length or more, compoſed of ſmaller ones which are alternate. Bractes to the lower partial panicles like leaves; the upper ones linear-lanceolate; and thoſe to the outmoſt branchlets of the panicle ſmall and linear. Flowers very large, white, fugacious, odorous: calyx ſmall, acutely five-cleft, ſpreading; petals ovate; ſtamens about thirty, much longer than the petals, with ſmall yellow anthers. Styles four or five, ſhorter than the petals. Capſules four or five, from upright parallel, a little reflexed at the top; crowned with the calycular receptacle and the withered remains of the ſtamens.

Native of eaſtern Siberia, in boggy woods, wet vallies, and on the banks of torrents; it is abundant as far as Kamtſchatka, along with the *ſalicifolia*. It flowers in Siberia at the beginning of july; is a very handſome ſhrub in plantations; and the hollow ſhoots are uſed for tobacco-pipes[g].

It was cultivated here in 1759, by Mr. Miller, and flowers in auguſt[h].

β. On the very lofty mountains about the lake Baical this ſhrub becomes gradually ſmaller, till towards the ſummit it is ſcarcely higher than a ſpan, and woody only for a finger's length. The leaflets are leſs, very elegantly gaſh-ſerrate, and almoſt pinnatifid, with the pinnules ſerrate all round; they are not ſo much pointed, and in pairs from five to eleven. The hairs are ſimple and none of them ſtarred. Panicle ſimple, conſiſting of three three flowered branchlets, and one below from the axil of the upper leaf. Flowers larger, with the ſtamens leſs elongated in compariſon with the petals[i].]

15. Root perennial. Stem annual, from three to four feet high. Leaves doubly pinnate; each having three or four pairs of oblong leaflets terminated by an odd one: they are two inches long, and almoſt an inch broad, ſerrate, and ending in acute points. Flowers diſpoſed in long ſlender ſpikes, formed into looſe terminating panicles; they are ſmall, white, and of two ſexes in the ſame ſpike.

[Gouan remarked this plant to be always polygamous-monoecious. Pollich ſays that the male flowers are on a diſtinct plant, and larger than the females. Scopoli, Haller, and Krocker agree with him and Linneus, in aſſigning dioecious flowers to this plant. Krocker ſays that the male flowers have the rudiment of a germ: and Haller, that he was informed by Ludwig, that he had obſerved an androgynous ſpike in his garden. Thunberg affirms, that in his ſpecimen from Japan, the flowers were all hermaphrodite. He thus deſcribes the plant.—Stem ſcaly at the baſe, round, upright, herbaceous, wholly ſmooth. Leaves alternate, petioled, ſuperdecompound-ternate: leaflets on ſhort round petioles grooved above; the lateral ones ſmaller, ovate, acuminate, doubly ſerrate, ſmooth, paler beneath, nerved, an inch long and more. Racemes numerous, ſcattered, diſtich, ſeldom compound, a finger's length or more. Peduncles filiform, villoſe; pedicels one-flowered, very ſhort. Calyx half-five-cleft, with ovate blunt ſegments. Filaments ten, longer than the corolla. Styles two. Linneus ſays three: and that there are one or two ſeeds in each capſule. According to Haller, there are three capſules with one ſeed in each. Pollich alſo ſays that the capſules are one-ſeeded. Scopoli, that there are four or five germs, and four ſeeds.

Pallas thus deſcribes the Siberian plant.—Root perennial. Stem ſuffruticoſe, three feet high or more, ſlender, ſmooth, ſtriated, ſcarcely branched. Leaves alternate, variouſly compound: leaflets ovate, acuminate, doubly-ſerrate, pubeſcent on the nerve and petiole. The upper ſtem-leaves are often ſimply pinnate, conſiſting only of two pairs with an odd leaflet: the lower ones are made up of two which are quinate-

[d] Pallas. [e] Idem. [f] Hort. kew. [g] Pallas. [h] Hort. kew. [i] Pallas.

Digitized by Google

pinnate, and of one between them compoſed of a terminating leaflet, two lateral ones which are ternate, and two ſimple pinnas which are interpoſed between them. Panicle terminating, very handſome, hairy, cloſe, compoſed of alternate partial panicles, of which the lower one is axillary, and the upper ones are accompanied by a leaflet or linear bracte: each ſpike of the panicles is ſeſſile, filiform, from an inch to two inches in length, compoſed of cluſtered ſubpetioled flowers. In ſome panicles theſe are all male, in others all female on a ſeparate plant; the panicles of the latter are leſs abundant, and the flowers are nodding. In the males, the calyx is acutely five-cleft; the petals larger, white, patulous; the ſtamens about fifteen, longer than the petals, pale; the centre bald. In the females, the petals are ſcarcely larger than the calyx; germs three, parallel, oblong, length of the petals, with a longiſh ſtyle, and a headed ſtigma. Capſules nodding with reflexed peduncles, in threes, oblong-ſubventricoſe, mucronate with the ſtyle, gray, two-ſeeded. Seeds linear-acute, ſlender.

Native of Germany, Auſtria, Carniola, Dauphiné, Switzerland, Piedmont, Siberia, Japan, Virginia. It flowers here in june and july, and was cultivated in 1633, by Mr. John Tradeſcant, ſen.[k]: where only Johnſon the editor of Gerarde had ſeen it.

16. Root perennial, conſiſting of oval tubers or ſolid lumps, hanging from the main body by threads, which has given occaſion to its common names of *Filipendula* and *Dropwort*: theſe tubers enable the herb to reſiſt drought, and render it very difficult to be eradicated. Stem erect, from a foot to a foot and half in height, angular, ſmooth, leafy, a little branched at top. Leaves alternate, interruptedly pinnate, ſerrate and jagged, ſmooth, compoſed of ſeveral pairs of leaflets, all of each ſet uniform or nearly correſponding in ſize; the terminating leaflet three-lobed. A pair of roundiſh united indented ſtipules, at the baſe of each leaf, embracing the ſtem. Flowers many in a cymoſe looſe erect panicle, cream-coloured often tipped with red, or red on the outſide. Styles from eight to twelve[l]. Capſules ten to fourteen[m].

It is an elegant plant, very common in high paſtures, on a calcareous ſoil, where it is ſometimes very ſmall. In gardens it grows very luxuriant, and has often double flowers. It flowers early in july. The whole herb is aſtringent[n]: and has been formerly uſed in medicine, but is now wholly neglected with innumerable others. Hogs are fond of the roots.

17. Root perennial, fibrous. Stems erect, three or four feet high, angular and furrowed, tinged with red, leafy, branched in the upper part. Leaves interruptedly pinnate: leaflets very unequal in ſize, ſharply ſerrate, clothed beneath with white down, the end one remarkably large and three-lobed. A pair of rounded ſerrate ſtipules are joined to the common leaf-ſtalk, and claſp the ſtem. Flowers white, in a large very compound cyme, the ſide branches of which riſe much above the central one. Styles and capſules five or ſix to eight, twiſted ſpirally.

Meadow-ſweet or Queen of the meadows abounds in moiſt meadows, about the banks of rivers, brooks and ditches, perfuming the air with the ſweet hawthorn-like ſcent of its plentiful bloſſoms from june to auguſt. The green parts of the herb partake of a ſimilar aromatic flavour, when rubbed or chewed, approaching to the taſte of orange-flower water, a flavour poſſeſſed in higher perfection by the American *Gualtheria*[o]. The flowers infuſed in boiling water, give it a fine flavour, which riſes in diſtillation. Sheep and ſwine eat the herb; goats are fond of it; kine and horſes refuſe it[p].]

A variety with double flowers, and another with variegated leaves are to be found in ſome gardens. The leaves and tops have been uſed in medicine.

Mr. Miller has a variety of the *Filipendula* which he received from Boerhaave, and conſidered as a diſtinct ſpecies, under the name of *anguſtifolia*. The leaves are much longer and narrower than thoſe of

[k] Hort. kew. [l] Smith. [m] Pollich and Scopoli.
[n] Smith. [o] Idem. [p] Withering.

the common ſort; ſome of the leaflets are two inches and a half long, and others not more than an inch. The flower-ſtalk riſes much higher, and ſuſtains a much larger bunch of flowers.

[18. Like the next ſpecies, but diſtinct by having the leaves tomentoſe underneath, with the ſegments acuminate; the flowers white, in a contracted branched corymb.

Native of eaſtern Siberia, in meadows and moiſt vallies, in the ſubalpine regions, beyond Baical, and eſpecially in Dauria. It has much of the habit, taſte and ſmell of our common Ulmaria[q].

19. This alſo has the ſtature and appearance of Ulmaria. The root ſmells ſweet, but the herb does not. The leaves are very nearly thoſe of Ulmaria, with the leaflets lobed. Flowers red. Fruit of Filipendula, not twiſted ſpirally but ſtraight[r]. It is probably a native of North America; Jacquin had it from Belgium. It differs from ours, ſays Pallas, in having the leaves naked beneath, and the flowers red.

It was not diſtinguiſhed from the preceding in the Supplement of the younger Linneus, and the Kew catalogue, where it is ſaid to have been introduced in 1765, by Meſſrs. Kennedy and Lee.

20. Root thick, white, black on the outſide. Stems two or three, a fathom high or more, as thick as the finger or thumb at bottom. Root-leaves very large, often a foot wide, and eight inches long, white with hairs beneath, five-lobed; lobes acute, doubly ſerrate. Petioles near the leaf have a few minute ſtipules. Stem-leaves ſimilar; upper three-lobed; uppermoſt ſubhaſtate or lanceolate: ſtipules at the baſe of the petioles, large, lanceolate or ſemicordate, toothed. Stem roundiſh or ſlightly three-ſided, hairy, deeply grooved. Cyme terminating, branched, ſcattered, very handſome. Flowers a little larger than thoſe of Ulmaria, with white ovate petals: calyx hairy, reflexed. Stamens fewer than twenty, often ten. Germs four to ſix, very hirſute; with a ſubcapitate ſtyle, ſhorter than the ſtamens. Capſules like ſilicles, parallel, hiſpid, gray, two-ſeeded; but ſometimes only one ſeed comes to perfection[s].

Willdenow remarks, that the petiole is furniſhed above with roundiſh leafy appendages; and that it ſeems to be allied to the next ſpecies.—Native of Kamtſchatka and Bering's iſland.

21. Stem herbaceous, ſtriated, erect, wholly ſmooth. Leaves alternate, five or ſeven lobed, beneath pale, and netted-veined: lobes oblong, acuminate, acutely and doubly ſerrate: petiole ſtriated, four times ſhorter than the leaf. Flowers white or red; the latter with four ſtyles. It differs from the *opulifolia*, to which it approaches neareſt in the leafing, in having the leaves five or ſeven-lobed, with the ſerratures acute; the panicle decompounded, and the ſtem herbaceous.—Native of Japan[t].]

22. Root perennial. Stalks annual, about a foot high, ſending out branches from the ſide the whole length. Leaves for the moſt part trifoliate, but ſometimes ſingle or in pairs; they are about an inch and half long, and half an inch broad, ending in acute points, ſharply ſerrate, of a bright green above, and pale beneath. Flowers in looſe terminating panicles, on ſlender peduncles: petals long, lanceolate, ſpreading. Stamens no longer than the tube of the flower.

[This ſpecies, ſays Mr. Curtis, is one of the moſt elegant, and when it grows in perfection is certainly a moſt delectable plant. Another circumſtance, that of being rather ſcarce, will recommend it to many. It increaſes little, is propagated with difficulty, and is liable to be loſt unleſs planted in a ſoil and ſituation quite favourable.

Native of North America. Cultivated by Mr. Miller in 1758. It flowers in june and july[u].]

PROPAGATION AND CULTURE.

The ſhrubby ſorts may be propagated from ſuckers, which are ſent forth in plenty from the ſtems of the old plant, in ſome of them; or by laying down the tender branches, which when rooted, ſhould be tranſ-

[q] Willdenow and Pallas. [r] Linn. ſuppl. [s] Pallas.
[t] Thunberg. [u] Hort. kew.

planted

Digitized by Google

planted out in rows at three feet diſtance, and the plants a foot aſunder in the rows. In this nurſery they may remain two years, obſerving to keep the ground clean from weeds, and in the ſpring to dig it up between the rows, that the roots may the more eaſily extend themſelves: but if they put out ſuckers, theſe ſhould be taken off. Afterwards they may be tranſplanted where they are to remain, among other flowering ſhrubs, obſerving to place them among other ſorts of equal growth. For layers, the branches muſt be laid down in autumn, and in one year they will take root.

Theſe ſhrubs require no other pruning, but to cut out all the dead branches and ſuch as grow irregularly; and to take off the ſuckers every year. If theſe be permitted to grow, they will ſtarve the old plants. The ground between them ſhould be dug every ſpring, to encourage their roots, and every third year a little rotten dung ſhould be buried in it, to make them flower ſtrong.

The herbaceous ſorts may be propagated by ſeeds, or by parting the roots in autumn.

22. Sow the ſeeds on a ſhady border ſoon after they are ripe, for if they are ſown in the ſpring, the plants will not come up till the year after, and many times fail. Remove the plants in autumn, when the leaves begin to decay, either where they are to remain, or into a nurſery-bed, where they may grow a year or two to get ſtrength. This plant loves a ſhady ſituation, and a moiſt light ſoil.

[It is uſually increaſed by parting the roots; poſſibly theſe might grow when made cuttings of. The beſt ſituation for this plant is a north border. It ſhould be planted in a light bog or peat earth, or a mixture of one of theſe with hazel loam*.

Petioles round ſix-paired, leaflets ſerrate ribbed.]

DESCRIPTIONS, &c.

1. The uſual height of this tree is ten or twelve feet, and the ſtem is as large as a man's leg, ſending out branches towards the top, covered with a gray bark; theſe are deſtitute of leaves for ſome months, and in the ſpring, before the leaves appear, many purple flowers come out from the ſide of the branches; theſe are ſucceeded by fruit like Plums, having a luſcious thin pulp, covering a large fibrous ſtone. The leaves which come out afterwards are unequally pinnate, with four or five pairs of leaflets, about an inch long, and half an inch broad.

[Jacquin deſcribes it as an ugly tree, varying much in height, and ſometimes thirty feet high. The bark is thick, and the wood whitiſh and brittle. Trunk upright. Branches thick, few, irregular. Leaves pinnate, alternate, ſhining, moſtly at the ends of the branches, falling off eſpecially when the fruit is ripening: leaflets ſubovate, entire or ſerrate above the middle, veined, on very ſhort petioles, varying in ſize, about ten on each ſide, with an odd one. Racemes ſhort, placed without order, often pretty cloſely, on the branches; but inſtead of theſe there are ſometimes peduncles with one, two or more flowers. Theſe are ſmall and red: the ſegments of the calyx blunt, roundiſh, concave; the petals blunt, and concave at the end; ſtigmas ſimple. Rind of the fruit purple, yellow, or variegated with both; pulp ſweet ſlightly acidulated, yellow, thin, having a ſingular but not unpleaſant taſte, and a ſweet ſmell. It varies in form; being oblong, ſubovate, very blunt at the end, or with a large appendix there. The ſeed ſcarcely ever ripens, but it is ſo eaſily increaſed by cuttings, that if a branch laden with young fruit be ſet in the ground, it will grow, and the fruit will ſoon come to maturity. Hence in St. Domingo, they make hedges of the boughs, which flower and bear fruit in a few months. If the tree be headed, it puſhes out very long upright branches, with numerous leaves ſcattered the whole length, and puts on an appearance ſo different, as hardly to be known for the ſame tree.

Gærtner

Digitized by Google

Gærtner deſcribes the drupe as being only one third of the ſize of that in the laſt ſpecies, ovate, narrowed upwards, ſhortly acuminate at the end: pulp in the old fruit fungous, rufeſcent: ſhell woody, muricate with laminæ and fibres variouſly netted and anaſtomoſing, neither lobed nor peduncled, but cohering all over, though with hollows here and there: cells five, connected together, and with the other ſubſtance of the ſhell; in each two germs on a thick umbilical chord common to both; only one of theſe ripens into a ſeed, and this is ovate-oblong, compreſſed like a lens, the colour and conſiſtence of an Almond.

Browne deſcribes it as a ſmall ſpreading tree, which ſeldom riſes above ten or twelve feet in height; its foliage is of a dark gloomy green, and it generally begins to ſhoot as the bloſſoms fall. It is cultivated by many for the ſake of the fruit, which is pretty pleaſant, although not held in any great eſteem in Jamaica, where they are always furniſhed with a great variety of the richeſt fruits.

There is a variety of this fruit, called the *Leather-coat*, from the appearance of its ſkin; but this proceeds from the dry ſoil in which it is produced.

In this, and many other American bacciferous (drupiferous) plants, where the cup (calyx) ſtands under the germ, the embryo is always ſurrounded by a fleſhy navel, which ſwells as that increaſes, and forms the pulp gradually about it.

Native of South America, whence it has been tranſplanted into the Caribbee iſlands; it is very common in St. Domingo, common in Jamaica, Curaçao and St. Martin's, but ſcarce in moſt of the others, according to Jacquin.]

2. This riſes to the height of thirty feet or more, ſending out many crooked irregular branches, which are deſtitute of leaves for ſome months: the branches have a light-coloured bark, and unequally pinnate leaves, with four or ſix pairs of leaflets near two inches long, and an inch broad, having deep longitudinal veins. The flowers come out before the leaves appear; and are ſucceeded by yellow Plums an inch or more in length, growing in a ſort of raceme: they have large fibrous ſtones with a thin covering of fleſh.

[Jacquin deſcribes it as a tall elegant tree, with a very wide branching head. Bark aſh-coloured and full of clefts. Wood whitiſh, ſmooth, not durable, fit only for fuel and making ſtoppers. Leaves pinnate, alternate, ſubfrondoſe, with a round rib, a foot long: leaflets for the moſt part eight, with an odd one, ovate-oblong ending in a blunt point, ſmooth, quite entire, petioled, the middle ones about three inches long, the outer ſhorter. Racemes looſely panicled, ſomewhat yellow, length of the leaves, terminating. Flowers very numerous, ſmall, whitiſh, and ſeſſile: calyx five-toothed, acuminate; petals ſublanceolate, acute, ſpreading very much; anthers erect; ſtigmas compreſſed and bilamellate. Very few fruits ſucceed this abundance of flowers in each raceme, being much expoſed to the winds by their great height. They are yellow, with ſometimes a ſlight mixture of redneſs, ſweet-ſmelling, covered with a thin ſkin, the ſize of a pigeon's egg, having within a little ſucculent acidulous pulp, and a very large nut; eaten by children, and ſome of the inhabitants, but making an excellent food for hogs. As the branches or cuttings grow ſo readily, it is uſed by ſome for hedges: and a tree or two is frequently planted in paſtures to afford ſhade to the ſheep.

Gærtner ſays, that the drupes in his ſpecimens were perfectly ovate, the ſame ſize as in the preceding, or near an inch and half long, very indiſtinctly five-cornered, the corners being formed by the back of the cells: ſkin fibrous, tough, in the old fruit hard: pulp ſmall, ſpongy: ſhell as in the preceding. Seeds ſolitary, long, narrow and as it were roundiſh, ferruginous. Seldom more than one cell is fertile.

According to Browne, the filaments ſtand upright, and grow in an even circular order round the germ; the ſtyles are always four, compreſſed, and enlarged at the top.

Native of all the Caribbee iſlands, and the neighbouring continent. Mr. Miller cultivated both this and the preceding in 1768.

β. The fruit of this variety is much eſteemed by ſome perſons in the Weſt Indies, and ſupplies the principal part of the food of the wild hogs in the ſeaſon [f].

3. Leaves a foot long, unequally pinnate; leaflets oblong, quite entire. Panicle racemed large [g]. Stamens commonly ten, but ſometimes eight. Nut five-celled, five-ſeeded [a].

This ſpecies is yet obſcure. It is the ſame with *S. amara* of Lamarck, *encycl.* 4. 245. which is figured by Rheede, *mal.* 1. *t.* 50?

Found in the Eaſt Indies by Koenig [b].

4. This is a tall ſhady tree, with a handſome ſpreading head. Trunk thicker than a man's body, upright, fifty feet high, flowering before the time of leafing in ſeptember. Branches diffuſed, ſpreading, round, with a brown rugged bark. Leaves ſcattered, cluſtered, pinnate, ſix-paired with an odd one: leaflets oblong-lanceolate, acuminate, very finely ſerrate, ſmooth, ſpreading, ribbed with a marginal nerve, and numerous parallel ſtraight veins, running from the rachis to the ribs at a right angle, dark green. Common petioles round, even, ſpreading, a foot long: proper nearly oppoſite, compreſſed a little, half an inch long. The general peduncle terminates the branchlets; it is round, even, almoſt upright, the length of the common petiole. Raceme large, compound. Partial peduncles alternate, round, ſmooth, horizontal, the upper ones gradually ſmaller, aſcending: pedicels one-flowered, ſcattered, very ſhort. Flowers ſmall, greeniſh-yellow. Calyx inferior, very ſmall, five-parted; ſegments equal, acute, pale green. Petals lanceolate, ſpreading very much, interpoſed between the ſegments of the calyx. A fleſhy yellow, toruloſe ring ſurrounds the germ, which is probably the nectarium. Germs five, ſmall, globular, united at the baſe. Styles cylindric, approximating at the baſe, recurved at the top, of the ſame length with the ſtamens. Drupe oval, obtuſe, large, very ſmooth, of a golden colour, and a ſomewhat nauſeous fetid ſmell: outer ſhell very thin, dotted; pulp fleſhy, ſucculent, ſweet, aromatic, fragrant: nut hard, woody, ovate, echinate all over with hard pungent fibrils, five-celled with membranaceous partitions: kernels ſolitary, ovate, compreſſed, the greater part abortive [c].

Gærtner deſcribes the fruit as a ſuperior, berried, oval drupe; with a tough ſkin formed of the capillary fibres of the ſhell, or cohering with them: fleſh firmiſh, taſteful, like a rennet Apple: ſhell woody, fibrous, lobed, on a long peduncle, compoſed of five cells, which are ſeparate, free at the top and on the ſides, but at the baſe cloſely united into one body not only with one another but with the lobes of the ſhell: lobes moſtly five, angular inwards and interpoſed between the cells, but outwardly echinated and muricated variouſly with anaſtomoſing laminæ, many-ſhaped points, and woody fibres. Seeds ſolitary, reſembling Almonds, ovate-attenuate, compreſſed a little, rufeſcent, faſtened to the bottom of the cells.—This is eaſily diſtinguiſhed from the other ſpecies, by its peduncled ſhell, and cells remote both from each other and from the axis [d].

Cultivated in the Society and Friendly Iſlands of the South Sea, eſpecially in Otaheite. The golden fruit hangs in little nodding bunches, and is eſteemed one of the moſt taſteful and wholeſome; it has almoſt the ſame flavour with the Ananas, and not only aſſuages thirſt, but is given to the ſick without diſtinction [e]. It has been introduced by the French into the iſland of Mauritius.]

PROPAGATION AND CULTURE.

Theſe plants grow eaſily from cuttings planted in pots filled with rich light earth, and plunged into a moderate hot-bed, covering them down either with bell or hand glaſſes, to exclude the external air, and

[f] Browne. [g] Linn. ſuppl. [a] Retz. from Koenig.

[e] Forſter.

ſhading

shading them from the sun. The best time for this is in the spring, before the plants put out their leaves.

They may also be propagated by the stones, if they are brought over fresh. Put them into small pots, filled with the same rich earth, and plunge them into a hot-bed of tanner's bark, observing duly to water the earth, and in six or seven weeks the plants will appear. Treat them afterwards in the same way as the Annona, keeping them constantly in the tan-bed in the stove; and when they are destitute of leaves give them but little water.

Whorls many-flowered ſubſpiked, upper lip bifid with the little ſegments acute, leaves broad cordate wrinkled hairy.

DESCRIPTIONS, *&c.*

1. Root perennial, creeping but not very extenſively. Stems about two feet, or from one to three feet high, upright, little branched, ſquare, hairy, leafy. Leaves cordate-ovate, acute, ſtrongly ſerrate, veiny, hirſute on both ſides, thin and pliable when handled, of a deep dull green; leaf-ſtalks hirſute, lower ones the length of the leaves, but ſhorter upwards and gradually diminiſhing to lanceolate entire bractes. Spike erect, terminating, leafy at the baſe, bracted above, conſiſting of many ſeparate whorls of ſix flowers each. Calyx browniſh, hiſpid, with five large ſharp teeth. Corolla of a deep blood-colour, prettily marbled about the orifice with a darker hue intermixed with white; tube cylindrical, with a ſmall pouch on the under ſide near the baſe, ſimilar to what may be obſerved in ſome ſpecies of Origanum. This herb has a pungent fetid ſmell when rubbed, approaching to that of Black Horehound. Being one of thoſe that powerfully affect the nerves, it might prove no contemptible ſtimulant, if judiciouſly uſed[f]. Toads are thought to be ſond

[f] Smith brit. Engl. bot. Curtis.

of

Digitized by Google

of living under its ſhade. Sheep and goats eat it; horſes, cows and ſwine refuſe it. The herb will dye yellow [g].

Frequent in hedges and other ſhady places; flowering in july and auguſt.

2. Root perennial. Stems ſeveral, decumbent at the baſe and then aſcending, ſcarcely a foot high, very hairy. Leaves an inch and half long, remote, veined, hairy on both ſides, with large blunt teeth: petioles hirſute, the lower ones twice as long as the leaves: the floral leaves ſeſſile. Whorls ſubſpiked, approximating. Spike two inches long, hirſute. Bractes cordate, length of the whorls: lower ſerrate, upper quite entire; all terminated by a ſoft ſpinule, as are alſo the ſegments of the calyx. Corolla purple, with the upper lip pubeſcent [h].—According to Desfontaines, pale roſe-colour, the ſame ſize as in St. ſylvatica; with the upper lip quite entire, the lobes of the lower rounded and entire, the middle one double the ſize of the ſide ones: anthers purple. Seeds brown, ovate-three-ſided.

L'Heritier remarks, that it differs from *ſylvatica* in having rounder leaves, crenate not ſerrate, ſomewhat hoary:—from *hirta* in having the upper lip entire.

Found in the mountains Zouwans of Tunis by Desfontaines and Vahl; and in the fiſſures of mount Atlas by the former; flowering in may.

Introduced about 1777, by Meſſrs. Gordon and Græfer. It flowers here from may to july [i].

3. Root perennial, creeping to a great extent; the extremities at the cloſe of ſummer becoming tuberous. Stems two feet high, upright, hollow, four-cornered, the ſides flattiſh, the corners rough with hairs pointing downwards; the joints alſo are hairy and purple. Leaves acute, ſerrulate, ſilky-haired above, woolly beneath, netted-veined and ſomewhat wrinkled, widening at the baſe and embracing; lower on ſhort petioles: a pair of ſmall leaves under each whorl, the uppermoſt quite entire. Spike ſix or eight inches high, formed of many whorls, in each of which, according to Linneus, are ſix flowers; but Curtis ſays ten, eight placed circularly, and one on each ſide above them; (Haller and Pollich ſay, from ſix to twelve; Scopoli ſix, but that he has a variety with ten.) Calyx purpliſh, beſet with fine hairs terminating in ſmall globules, marked with ten raiſed lines, the teeth nearly equal and pointed. Corolla pale reddiſh purple: tube crowned internally with hairs; mouth marked with two prominent dots at the baſe of the upper lip; lower lip beautifully variegated with white and purple. Filaments appearing hairy when magnified, thickeſt in the middle, reddiſh and ſhining: anthers purpliſh black, but the pollen white [k].

Native of Europe in marſhes, on the banks of rivers, in watery places, by road ſides and in corn fields, eſpecially in moiſt ſituations; flowering in july and auguſt. It behoves the farmer to know it, ſays Mr. Curtis, as a very noxious plant in many corn fields, increaſing much by its roots, and alſo by ſeed. If Linneus's information be accurate, that ſwine are fond of the roots, thoſe animals might be turned into fields that abound with this plant, after the crop is off, to great advantage.

4. Root perennial. Colour of the plant duſky. Leaves greeniſh yellow, with the ſerratures dark-cartilaginous at the point: the upper floral ones ovate, with the margin flat and quite entire. Whorls involucred, as in *germanica* and *cretica*. Corollas dull purple, with the upper lip horizontal, not erect as in them: the lower lip alſo is not reflexed at the ſides [l].

Stem often not branched. Leaves ſoft, wrinkled, hirſute, ſerrate, petioled, cut next the petiole; the lower cordate, the upper elliptic-lanceolate. Whorls denſe, but much leſs ſo than in *germanica*, with fewer flowers. Awns of the calyx long. The herb has the ſmell of Baum [m].

Scopoli remarks, that the teeth of the leaves are terminated by a gland; that the whorls have fourteen flowers; and that the calyxes are nerved, rigid and peduncled.

Stem from two to three feet high, erect, ſhining, often livid at the baſe, villoſe, ſlightly grooved. Leaves oblong-cordate, earletted as it were at the baſe, the ſerratures withering and brown at the points; the uppermoſt often quite entire, on ſhort petioles or ſeſſile, not cut out at the baſe, lanceolate; the root-leaves on long firm petioles. Whorls very cloſe involucred with hairy coloured briſtles bent upwards. Calyx erect, hairy at the corners; the teeth awned, hirſute, the two lower longer than the other three. Upper lip of the corolla almoſt incumbent, bifid, ciliate with white hairs within and without: the two ſide ſegments of the lower lip reflexed, the middle ſegment crenulate, not reflexed at the ſides, ſinuate in the middle, all pale purple with one blood-red line running along them [n].

Native of Germany, Switzerland, Carniola, Italy and the South of France. Cultivated in 1759 by Mr. Miller. It flowers from june to auguſt [o].

5. Root perennial. The whole herb remarkably inveſted with a white ſoft ſilky pubeſcence, in which reſpect it is only inferior to the garden *Stachys lanata*, a ſpecies that differs from it beſides in having blunter leaves, with ſtems procumbent at the baſe and taking root at that part. The ſtems of our plant are erect. Leaves ovate, rather pointed, ſharply crenate, reticulated with veins, ſilky above, moſt woolly beneath, the radical ones on long petioles, the reſt ſmaller and nearly ſeſſile: they feel very thick and ſoft like woollen cloth. Whorls axillary, numerous, many-flowered, (forty or fifty *Pollich*; forty *Scopoli*:) the upper ones crowded. Bractes linear; both they and the calyxes very denſely villoſe. Corollas purple within, ſtreaked about the mouth with white; their outſide whitiſh and very downy, eſpecially the upper lip. Stamens hairy. Seeds roundiſh, black [p]. It varies with a white flower, and with narrower leaves [q].

Native of Denmark, Germany, Switzerland, France, England, Auſtria, Carniola, Piedmont, Siberia.—In corn fields and by way ſides, on the limeſtone ſoil of Oxfordſhire, it was long ago obſerved, eſpecially towards Witney, in 1632 by Mr. Buckner, an apothecary of London. Mr. Woodward found it between Blenheim and Ditchley: Dr. Sibthorp, near Witney, Stonesfield, and between Woodſtock and Enſtone: and Dr. Goodenough, at Brizenorton. It has alſo been found four miles ſouth of Grantham near the London road, oppoſite Eaſton: and lately by the Rev. Mr. Hemſted, on a hill two miles from Bedford. It flowers in july [r].

6. Native of Carolina. Introduced about 1762. It flowers in june and july. Perennial [s].

7. Root perennial. Stems ſomewhat woody at bottom, whence proceed herbaceous branches or ſtems a foot high or more, four-cornered, little branched, erect, covered with a very thick white wool; as are alſo the leaves on both ſides, the bractes and calyxes. Leaves ovate-oblong, ſharpiſh, three or four inches long, petioled, minutely crenulate, veined. Whorls cloſe, ſhorter than the floral leaves, approaching at top. Calyx ſcarcely angular, divided to one third of the length; ſegments ovate, acuminate, almoſt equal. The whole corolla ſo reſembles that of *St. germanica* as ſcarcely to be diſtinguiſhed from it, except that in the *germanica* the back of the upper lip is bearded with hairs ſtretched beyond it, whereas in this it is only a little hirſute: the colour alſo is ſomewhat deeper. It has not much ſmell. The ſeeds were ſent from Aſtracan [t]. It is a native of Siberia; and was introduced in 1782, by William Pitcairn, M.D. It flowers moſt part of the ſummer [u].

8. This reſembles the *germanica*, but the plant is lurid, and rough-haired without any white wool. The floral leaves are lanceolate, and ſerrate-waved, but not reflexed or arched as in *germanica*.

Native of the iſland of Crete or Candia [x]. Cul-

S T A

tivated in 1723, in the botanic garden at Chelſea. It flowers from june to auguſt, and is perennial [r].

9. Native of Hiſpaniola [s].

10. This is a little ſhrub, a foot high, very much branched, wholly ſmooth: branches oppoſite, dichotomous at top, four-cornered; the laſt branchlets end in a ſpine. Leaves quite entire, ſomewhat veined; the lower lanceolate, attenuated into the petiole, ſcarcely an inch long: thoſe on the branchlets linear, ſeſſile, length of the interſtices. Peduncles on the upper branches, ſolitary, one-flowered, ſhorter than the leaf, with two linear leaves at top, almoſt the length of the calyx. Teeth of the calyx lanceolate, acute. Corolla villoſe on the outſide [a].

Moriſon ſays that it is annual, a long ſpan in height, branched from the very bottom. Leaves crenate and moderately hairy. Flowers white. The whole plant clammy, with a ſtrong bituminous ſcent. Zanoni obſerved it in Candia.—Cultivated by Mr. Miller in 1759.

11. Stem very much branched. Branches four-cornered, brachiate: branchlets rigid, ending in a ſpine. The whole plant hoary with white hairs preſſed cloſe. The lower leaves attenuated at the baſe, linear-lanceolate, an inch long, quite entire: upper ones linear, ſeſſile. Flowers on the extreme branchlets, axillary, ſolitary or in threes, ſmall. Calyxes pungent [b].

Native of Candia, in the weſtern part of the iſland, in very dry places, among Thyme: it is called by the countrymen there γαιδαρο θυμο or Aſſes Thyme [c].—Cluſius raiſed it from ſeed in 1597. Mr. Miller cultivated in 1768.

12. Stem very hairy. Leaves wrinkled, crenate, very cloſely hairy, ſoft, hoary, the upper ones ſeſſile. Whorls remote, many-flowered. Upper bractes ovate, quite entire. Calyxes very hirſute, aſh-coloured, pungent. Corolla yellow, with the upper lip very hirſute on the outſide [d].

Native of the Levant. Cultivated by Mr. Miller in 1768.

13. Stems ſhrubby, round, white-tomentoſe. Leaves alſo white-tomentoſe, ſoft, not very acute. Calyx ten-cornered. Upper lip of the corolla concave, entire, purple, with a deeper purple line along the edge: lower lip alſo purple, ſpotted with white at the throat: middle lobe larger, concave.

Native of Paleſtine [e]. In the appendix to the Species Plantarum Linneus adds, that the ſpikes are compoſed of ſix-flowered whorls, with ovate, tomentoſe, veined bractes; and acute calyxes. The ſame ſynonym from Volkamer is given both under this ſpecies and *Dracocephalum canescens*.

14. Root perennial. Leaves cordate-oblong, veined. Stem ſuffruticoſe, a ſpan high, erect, pubeſcent. Spike compoſed of interrupted whorls; with bractes the length of the flowers. Whorls ſix-flowered. Calyxes woolly, ſharp, ſcarcely awned. Corollas yellow [f].

Native of the South of Europe, on the coaſt. Cultivated here in 1714. It flowers in july [g].

Reſpecting the colour of the corolla, Dillenius remarks, that the upper lip is paler than the lower, which towards the throat is variegated with ſome ſmall purple ſtreaks and dots; and that the upper lip has an oblong purple ſpot on each ſide near the ſtamens. He will by no means allow *Sideritis heraclea* of Columna to be this plant. Linneus ſays there is a ſimilitude, but the flowers in Columna's plant being purple, it is doubtful whether they are the ſame.

15. Root perennial. The whole plant hairy. Stems annual with oppoſite branches. Leaves oblong-cordate, very bluntly ſerrate, wrinkled, ſometimes ſhorter than the petioles. Flowers on ſhort peduncles and ſolitary, in the axils of the leaves, on the upper part of the branchlets, in form of a looſe ſpike. Calyx cloven half way down into ſetaceous-acuminate ſegments. Corolla incurved, three times as long as the calyx; the upper lip villoſe on the outſide, erect, arched, obovate, entire, the length of the lateral ſegments of the lower lip; the middle ſegment of which is very wide, flat, twice as long as the two ſide ones, and crenate in front [h].

Stem a palm high, erect or diffuſed. Habit of *Lamium purpureum*, ſubhiſpid-hairy. Leaves cordate, deeply and bluntly ſerrate, wrinkled, ſhining, ſubvilloſe, ſhorter than the petioles. Spikes terminating, interrupted, made up of whorls, which have two flowers oppoſite or one on each ſide. Calyx almoſt equal, ſlightly awned. Tube of the corolla curved; upper lip erect, arched, ſhort, villoſe; lower very large and ſtretched out, middle ſegment very wide, flat and crenate, the ſide ones revolute. Stamens ſcarcely longer than the tube, with two-parted anthers [i].

Native of the Cape of Good Hope. Introduced in 1770, by Monſ. Richard. It flowers from april to july [k].

16. Root perennial. Stems proſtrate, four-cornered, hollow, brittle with hairs very thinly ſcattered over them. Leaves petioled, cordate, hairy on both ſides, veined: lower bluntly ſerrate, obtuſe, on longer petioles; upper acute and acutely ſerrate. Flowers in whorls, three on each ſide, without an involucre. Calyx awned. Tube of the corolla ſhorter than the calyx, incurved: upper lip arched, cloven half way, the clefts divaricating and obtuſe; lower very blunt, flat, indiſtinctly three-lobed, with a ſegment ſo ſmall as to be ſcarcely apparent on each ſide of the baſe. At the edge of the baſe of the upper lip, and on the diſk of the baſe in the lower are purple dots [l].

According to Desfontaines it is annual. Stems hirſute and branched. Bractes ovate, longer than the calyx, leafy, mucronate at the tip; the lower crenate, the upper quite entire. Whorls from four to ſix-flowered. Calyx villoſe, bell-ſhaped, with long, awl-ſhaped, almoſt equal teeth, mucronate-ſpiny at the tip. Tube of the corolla ſhorter than the calyx, bowed: upper lip erect, obtuſe, cloven half way: lower three-lobed.

Native of Spain, Italy, the Levant, and Barbary about Tunis.—It was cultivated in the Apothecary's garden at Chelſea in 1725. It flowers from june to auguſt [m].

17. Root perennial, branched. Stems ſeveral, two feet high, aſcending at the baſe and then upright, ſharply four-cornered, green, very hirſute with white hairs. Leaves petioled, cordate, obtuſe, crenate, veined, inodorous, ſoft on both ſides with ſcarcely viſible hairs, on a hirſute petiole: upper ones more oblong and ſharper: uppermoſt lanceolate and very ſharp. Whorls ſix-flowered; flowers ſeſſile, with little and a not unpleaſant ſmell. Calyx ſomewhat villoſe, green; ſegments lanceolate. Corolla roſe-purple: upper lip quite entire; diſk of the lower lip above the throat pale dotted with purple. The fruiting calyx increaſes, and becomes bell-ſhaped with the border ſpreading.

Native of the Canary iſlands, where it was firſt found by Maſſon [n].

18. Stem erect, a ſpan high, ſimple, hirſute. Lower leaves connate at the baſe, upper diſtinct, ſeſſile; all blunt, ſmoothiſh above, ſoftly hairy beneath: floral leaves cordate-ovate, reflexed, ſhorter than the whorls, ſmooth on the inner ſide. Spike the length of the ſtem, compoſed of remote whorls. Calyxes very hirſute: ſegments awl-ſhaped, ſpreading very much, three times as long as the calyx. Corolla purple. It is well diſtinguiſhed by the very long ſpreading ſegments of the calyx.—Native of the Levant [o].

19. Root perennial. Stems ſtiffiſh, with hairs thinly ſcattered over them. Leaves ſubpetioled, cordate, elliptic or often lanceolate, deeply crenate, rugged with thinly ſcattered hairs on both ſides, ſomewhat wrinkled. Spikes terminating, growing out into diſtant whorls, each having about ten flowers. Calyxes ſubſpiny. Flowers yellow [p].

Native

Digitized by Google

Native of the South of Europe. Cultivated in 1758 by Mr. Miller. It flowers from june to auguſt [9].

20. This has the air of the preceding. Root perennial. Stems a foot high, rigid, hairy, branched. Leaves hairy, ſomewhat wrinkled, ſhorter than the internodes; lower petioled, middle and upper ſeſſile. Whorls diſtinct, the lower ones more remote. Flowers ſubſeſſile. Bractes ſeſſile, lanceolate-mucronate or cordate-ovate acuminate, pungent at the end, length of the calyxes, quite entire. Calyx very hirſute, with the ſegments lanceolate, almoſt equal, ſpreading, rigid, ſpiny at the end. Corolla purple, villoſe, the ſame ſize as in *St. recta:* tube the length of the calyx, hairy: upper lip erect, emarginate; lower three-lobed, hairy on the outſide, the middle lobe much the largeſt.—It differs from the preceding, to which it is allied, in having the calyxes very hirſute, ſpiny, and twice as big; the whorls ſix-flowered; the corollas purple, with the upper lip emarginate. The leaves in *recta* are acute outwards, not dilated, the awns of the calyx ſoft, the whorls ten-flowered, and the corollas yellow [1].

21. Root annual. Lower leaves ovate, wrinkled, very blunt; middle ones oblong, petioled; thoſe above ſeſſile, lanceolate, three-nerved. Corollas yellow: upper lip recurved, emarginate, with the lateral edges ferruginous: calyxes mucronate but not thorny. The ſtem in mountainous ſituations is upright, in meadows procumbent. The ſtamens reflexed to the ſides indicate the genus [2]. Crantz's deſcription of *Stachys Betonica* belongs to this ſpecies [3].

Native of Germany, Auſtria, Carniola, Switzerland, Piedmont, and France. Cultivated in England in 1713. It flowers in july and auguſt [4].

22. Native of the Cape of Good Hope, where it was found by Maſſon; and introduced in 1774: it flowers in july. Shrubby [5].

23. Root ſmall, annual. Stem from a ſpan to a foot in height, among corn upright, but alone weak or procumbent, branched, ſomewhat hairy; branches brachiate. Leaves three-nerved at the baſe, widely crenate, ſomewhat hairy on both ſides, petioled except the uppermoſt. Flowers all in whorls. Calyx hairy, with the teeth ciliate. Corolla ſmall, ſcarcely exceeding the calyx, pale purple or fleſh-coloured: upper lip ſhort, blunt and entire. Filaments white below and purple above: anthers blackiſh; pollen yellow. Seeds greeniſh dotted with black [7].

Authors ſeem to have been at a loſs in what genus to place this humble plant: it does not appear to poſſeſs the ſtriking characters of any, or to afford ſufficient diſtinction for making it a ſeparate genus. As a ſpecies, the ſmallneſs of its flowers, the form of its leaves, and the place of growth, obviouſly diſtinguiſh it from any other Engliſh plant [8].

Native of Europe, in corn fields, in a gravelly or calcareous ſoil: flowering from june to auguſt.

24. Introduced about 1775 by William Pitcairn, M. D. It flowers in june and july. Shrubby.—Native place of growth unknown [9].]

PROPAGATION AND CULTURE.

Moſt of the ſorts are hardy, and may be propagated by ſeeds ſown in march upon a bed of light freſh earth: when the plants come up, ſet them out into beds ſix inches aſunder, watering them till they have taken root, and keeping them clear from weeds. At michaelmas tranſplant them where they are to remain, in an open ſituation, and upon a dry light ſoil, not over rich. The ſummer following theſe plants will flower, and in auguſt their ſeeds will ripen: many of them die ſoon after. Some continue ſeveral years, and may be increaſed by parting the roots.

St. ſylvatica, paluſtris and germanica are wild creeping plants, and ſpread very much where they have liberty.

Annua and arvenſis are annual, the reſt are perennial.

Leaves awl-ſhaped erect tomentoſe.]

DESCRIPTIONS, *&c.*

1. This riſes with a ſhrubby ſtalk about three feet high, and divides into ſeveral branches. Leaves long, taper, woolly, thinly ſet upon the branches. Flowers terminating in ſingle heads, which are pretty large, and have ſcaly calyxes ending in recurved ſpines. The florets are yellow. [Style bifid. Calyx ſcarioſe. Seed-down feathered, connate at the baſe. Anthers tailed[a].

Native of the Cape of Good Hope, whence it was long ſince introduced into the Dutch gardens. Mr. Miller cultivated it in 1759.]

2. This is a biennial plant, with the ſtalks rarely above a foot high. Leaves narrow and very woolly, oppoſite or alternate, having much the appearance of one ſort of *Elichryſum*. Flowers terminating. Calyxes long, with the ſcales ending in acute recurved points: florets a little longer than the calyx. It flowers in july.

[Linneus remarks, that it is a ſingular plant, intermediate as it were between the Serratulas, Gnaphaliums, and Stæhelinas: hence he named it *dubia*.—Seed-down hairy, connate at the baſe. Stem and leaves beneath tomentoſe.

Native of Spain, the South of France, and Italy. Mr. Miller cultivated it in 1759.

3. Calyx imbricate with awnleſs ſcales. Chaffs many-parted. Seed-down branched and feathered. Anthers as in *Inula*, toothed at the baſe. Florets naked, neuter[c].—Leaves petioled, oval, quite entire, ſilky and ſilvery beneath[d].

Root black, with long black fibres. Stem ſimple, erect, ſtriated, ſmooth, almoſt naked. Root-leaves ovate, ſmooth: ſtem-leaves narrower, lanceolate, ſubſerrate, fewer, and only towards the lower part. Flower terminating: ſcales of the calyx lanceolate, naked, blackiſh at the tip; the upper ones pellucid and yellowiſh. Corollas purple[e].

Native of the South of France, and the iſland of Candia.

In alpine ſituations it varies with a ſtem two feet high and more.

4. Native of the Levant.

5. Stem ſhrubby, rigid, very much branched. Branches alternate, round, ſtriated, ſmooth. Leaves alternate, ſeſſile, rigid, pungent, remote, ſpreading very much, ſomewhat ſtriated, having a ſpinule on each ſide at the baſe. Flower ſolitary at the end of the branches, with a pair of ſmall leaflets at the baſe. Calyx before flowering cylindric, but afterwards turbinate, imbricate, ſmooth: ſcales linear-oblong, ending in a dagger-point. Seeds hairy, three-ſided: down length of the calyx, gray, appearing to be very finely

[a] Linn. ſyſt. [c] Schreber. [d] Linn. mant. [e] Gcr. prov.

toothed when examined by a magnifier. Receptacle with very ſhort, briſtle-ſhaped chaffs.—Native of Egypt.

6. This is a low ſtiff and very branching ſhrub. Branches round, hoary, blunt. Leaves oblong, ſeſſile, widened on each ſide towards the middle by a ſmall horizontal lobe, very blunt, but acute at the baſe, hoary eſpecially beneath, and ſometimes there is a ſmall toothlet in the axil of the lobules. Flowers towards the end of the branchlets, ſolitary, ſeſſile. Calyx of the ſame form as in *ſpinoſa*, with linear keeled ſcales. Seeds villoſe: down ferruginous, ſimple, very finely toothletted beyond the calyx, and ſomewhat rigid. Receptacle ſcarcely chaffy.—Native of Egypt[f].

7. This is a tree or a ſhrub, with ever-green ſhining leaves, and round, pubeſcent, cloſely leaved branchlets, flowering at the top. Leaves ſpreading, an inch long, cordate-ovate, obtuſe, a little rolled back at the edge, groſsly toothed, netted-veined, very ſmooth and varniſhed as it were above, denſely woolly and white beneath. Petioles thick, pubeſcent, curved in. Panicle terminating, ſubcymed, denſely woolly. Peduncles round. Bractes lanceolate. Calyx hemiſpherical, ſubcylindrical, imbricate or rather calycled: ſcales oblong, very denſely woolly on the outſide, membranaceous and naked above and along the edge, lacerate-ciliate at the tip; after flowering cloſely bent in, permanent. Florets numerous, yellow, funnel-ſhaped, five-cornered, ſmooth: border five-cleft, obtuſe, erect. Filaments capillary, white: anthers included, obtuſe, converging, cloven at the baſe and inſerted laterally into the filament, yellow. Germ oblong, quadrangular, ſmooth: ſtyle a little longer than the ſtamens, cloven at the top: ſtigmas divaricating, obtuſe. Receptacle flattiſh, denſely chaffy: chaffs ſhort, rigid, commonly bifid or trifid. Seeds form of the germ: down ſhorter than the corolla, feathered.

Native of New Granada, where it was found by Mutis[g].

8. This is a ſhrub, with proliferous, hoary, erect branches. Leaves alternate, ſubpetioled, diſtant, wedge-ſhaped or lanceolate, end-bitten and blunt, retuſe or three-toothed, ſomewhat white-tomentoſe beneath. Corymb compound, terminating. Calyx hoary, with very ſhort ſcales. Seed-down white, longer than the calyx.—Native of the Cape of Good Hope[h].

9. Native of the iſland of Crete or Candia.

10. Native of the Cape of Good Hope.]

PROPAGATION AND CULTURE.

1. Plant cuttings in any of the ſummer months, covering them cloſely with a bell or hand-glaſs. When they have made good roots, take them up carefully, and plant them in pots, filled with freſh light earth, not over rich, and place them in the ſhade until they have taken new root; then remove them to a ſheltered ſituation, and in autumn place them in the houſe. They do not require any artificial heat in winter, but ſhould have a dry air; their tender ſhoots being very ſubject to rot with damp.—This ſort does not always ripen its ſeeds in England. Several of the other ſpecies may have the ſame treatment, whenever they ſhall be introduced.

2. Sow the ſeeds upon a warm border of light ground in the ſpring, where the plants are deſigned to ſtand; for unleſs they are carefully tranſplanted when young, they do not bear removal well. The ſecond year they will flower, and if the ſeaſon prove favourable, the ſeeds will ripen, and the plants will decay ſoon after. This ſort will live through the winter in the open air, on a dry poor ſoil, and in a ſheltered ſituation; but in rich ground it becomes luxuriant in ſummer, and is therefore more liable to ſuffer from cold in winter.

STAPELIA. (*So named by Linneus, in memory of Bodeus a Stapel, a phyſician of Amſterdam, commentator on Theophraſtus*, 1644.)

Lin. gen. n. 307. *Reich. n.* 334. *Schreb. n.* 432. *Juſſ.* 146. *Jacqu. miſc.* 1. *t.* 3, 4.

Claſſ. 5. 2. Pentandria Digynia.

Nat. order of *Contortæ*. *Apocineæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-cleft, acute, ſmall, permanent.

COR. one-petalled, large, flat, thick, five-cleft beyond the middle: *ſegments* wide, flat, acuminate.

Nectary, five leaflets, ſpreading, linear, grooved, emarginate with a dagger point, oppoſite to the ſegments of the corolla.

Leaflets five others, faſtened alternately with theſe a little higher to the tube of the filaments, and running along it, vertical, bifid: *interior ſegment* erect, with the ſummit bent outwards; *outer ſegment* ſtraight, compreſſed.

STAM. *Filaments* five, united into a ſhort tube. Each *Anther* faſtened internally to the baſe of each vertical leaflet of the nectary, and wider than it, incumbent on the ſtigma, ſhort, two-lobed, two-celled, produced below on both ſides into an *earlet*, contiguous at the margin to each of the neighbouring anthers as far as the tip, and aſcending at the tip. Pollen united into ten corpuſcles, creſcent-ſhaped, flattiſh, aſcending obliquely into the cells of the anther, each on a very ſhort pedicel (with a tranſverſe baſe, incumbent on the upper margin of the earlet,) faſtened by pairs to five ſmall twin coloured tubercles, placed on the apex of the earlets, and adhering to the angles of the ſtigma.

PIST. *Germs* two, ovate, flat inwards. *Styles* none. *Stigma* common to both germs, large, placed on the tube of ſtamens, acutely five-cornered, flat above, obliquely truncate-excavated at the ſides for the reception of the anthers.

PER. *Follicles* two, long, awl-ſhaped, one-celled, one-valved.

SEEDS numerous, imbricate, compreſſed, crowned with a down. Receptacle free.

ESSENTIAL CHARACTER.

Contorted. *Neck.* a double little ſtar covering the genitals.

SPECIES.

Branches aſcending four-cornered flowering at the baſe, peduncles round length of the corolla, which is villoſe at bottom with the ſegments ovate ſharpiſh and villoſe at the edge.

[4. Stapelia ſororia.

Lin. ſpec. ed. Willd. 1. 1278. *Maſſon monogr.* 23. *n.* 39. *t.* 39.

Branches divaricating four-cornered flowering at the baſe, peduncles round longer than the corolla, which is very villoſe at bottom and wrinkled tranſverſely with the ſegments oblong acute villoſe at the edge.

5. Stapelia grandiflora. *Great-flowered Stapelia.*

Lin. ſpec. ed. Willd. 1. 1278. *Maſſon monogr.* 13. *n.* 11. *t.* 11.

Branches erect four-cornered club-ſhaped flowering at the baſe, peduncles thickened at the baſe ſhorter than the corolla, which is villoſe with the ſegments lanceolate-acuminate ciliate at the edge.

6. Stapelia ambigua.

Lin. ſpec. ed. Willd. 1. 1279. *Maſſon monogr.* 13. *n.* 12. *t.* 12.

Branches erect four-cornered club-ſhaped flowering at the baſe, peduncles many-flowered, corollas hiſpid with the ſegments ovate-lanceolate acute villoſe at the edge.

7. Stapelia pulvinata. *Cuſhioned Stapelia.*

Lin. ſpec. ed. Willd. 1. 1279. *Maſſon monogr.* 13. *n.* 13. *t.* 13.

Stem four-cornered decumbent, branches aſcending flower-bearing, bottom of the corolla raiſed and villoſe, ſegments roundiſh wrinkled acuminate villoſe at the edge.

8. Stapelia Aſterias. *Starry Stapelia.*

Lin. ſpec. ed. Willd. 1. 1280. *Maſſon monogr.* 14. *n.* 14. *t.* 14.

Branches erect four-cornered attenuated flowering at the baſe, peduncles length of the corolla, the ſegments of which are ovate-acuminate wrinkled revolute and villoſe at the edge.

9. Stapelia gemmiflora. *Bud-flowering Stapelia.*

Lin. ſpec. ed. Willd. 1. 1280. *Maſſon monogr.* 14. *n.* 15. *t.* 15.

Branches erect four-cornered flowering at bottom, peduncles length of the corolla, which is rugged with the ſegments ovate acute ciliate at the edge five-nerved above.

10. Stapelia divaricata. *Straddling Stapelia.*

Lin. ſpec. ed. Willd. 1. 1280. *Maſſon monogr.* 17. *n.* 22. *t.* 22.

Branches four-cornered attenuated divaricate-ſpreading flowering in the middle, peduncles longer than the corolla, which is ſmooth with the ſegments lanceolate acuminate rolled back and ciliate at the edge.

11. Stapelia rufa.

Lin. ſpec. ed. Willd. 1. 1281. *Maſſon monogr.* 16. *n.* 20. *t.* 20.

Branches four-cornered erect flowering at the baſe, peduncles ſhorter than the corolla, which is wrinkled and ſtarred at the bottom, with the ſegments lanceolate acuminate ciliate at the edge.

12. Stapelia acuminata.

Lin. ſpec. ed. Willd. 1. 1281. *Maſſon monogr.* 15. *n.* 17. *t.* 17.

Branches four-cornered aſcending flowering in the middle, peduncles ſhorter than the corolla, which is wrinkled, and the ſegments are ovate cuſp-acuminate ciliate at the edge.

13. Stapelia reclinata.

Lin. ſpec. ed. Willd. 1. 1282. *Maſſon monogr.* 19. *n.* 28. *t.* 28.

Branches ſpreading four-cornered flowering above the baſe, peduncles longer than the corolla, which has a raiſed bottom with lanceolate ſegments ciliate at the edge.

14. Stapelia elegans.

Lin. ſpec. ed. Willd. 1. 1282. *Maſſon monogr.* 19. *n.* 27. *t.* 27.

Branches diffuſed oblong roundiſh four-cornered flowering in the middle, peduncles longer than the corolla, which is hiſpid with a pentagon bottom and lanceolate ſegments ciliate at the edge.

15. Stapelia cæſpitoſa. *Tufted Stapelia.*

Lin. ſpec. ed. Willd. 1. 1282. *Maſſon monogr.* 20. *n.* 29. *t.* 29.

Branches procumbent four-cornered flowering above the baſe, peduncles length of the corolla, the ſegments of which are lanceolate acute revolute and ciliate at the edge.

16. Stapelia arida. *Dry Stapelia.*

Lin. ſpec. ed. Willd. 1. 1283. *Maſſon monogr.* 21. *n.* 33. *t.* 33.

Branches four-cornered erect flowering at the top, peduncles longer than the corolla, which has a circular bottom and oblong acute ſegments ciliate at the top of the margin.

17. Stapelia parviflora. *Small-flowered Stapelia.*

Lin. ſpec. ed. Willd. 1. 1283. *Maſſon monogr.* 22. *n.* 35. *t.* 35.

Branches four-cornered ſpreading flowering in the middle

on the outside of the teeth, peduncles longer than the corolla, the segments of which are lanceolate bluntish and ciliate at the edge.

18. Stapelia subulata. *Awl-shaped Stapelia.*
Lin. spec. ed. Willd. 1. 1283. *Forsk. cat. arab.* 108. *n.* 193. *t.* 7.
Branches four-cornered attenuated nodding flowering below the top, corollas nodding, segments oblong acuminate-cusped with the hairs pointing one-way.

19. Stapelia concinna. *Neat Stapelia.*
Lin. spec. ed. Willd. 1. 1284. *Masson monogr.* 15. *n.* 18. *t.* 18.
Stem four-cornered erect branched at top, branches spreading simple flowering at the base, peduncles length of the corolla, corollas hispid with the segments ovate acute ciliate.

20. Stapelia glandulifera. *Glandular Stapelia.*
Lin. spec. ed. Willd. 1. 1284. *Masson monogr.* 16. *n.* 19. *t.* 19.
Branches spreading four-cornered flowering at the base, peduncles longer than the corolla, which is covered with hairs glandular at the tip, with the segments ovate acute.

2. *Corollas five-cleft, segments smooth at the edge.*

21. Stapelia pedunculata. *Long-peduncled Stapelia.*
Lin. spec. ed. Willd. 1. 1284. *Masson monogr.* 17. *n.* 21. *t.* 21.
Branches four-cornered two or three-toothed at the tip flowering in the middle, peduncles twice as long as the branches, segments of the corolla lanceolate acuminate, at the base surrounded at the edge by pedicelled glands.

22. Stapelia aperta. *Open-flowered Stapelia.*
Lin. spec. ed. Willd. 1. 1285. *Masson monogr.* 23. *n.* 37. *t.* 37.
Branches four-cornered three or two-toothed at the tip flowering at the base, peduncles twice as long as the branches, corollas wrinkled, segments ovate obtuse smooth at the edge.

23. Stapelia Gordoni. *Gordon's Stapelia.*
Lin. spec. ed. Willd. 1. 1285. *Masson monogr.* 24. *n.* 40. *t.* 40.
Branches flowering at the top round tubercles, tubercles spiny, peduncles shorter than the corolla, which is five-toothed flat and wheel-shaped.

24. Stapelia pilifera. *Hairy-tubercled Stapelia.*
Lin. syst. 260. *Willd.* 1. 1286. *suppl.* 171. *Masson monogr.* 17. *n.* 23. *t.* 23. *Thunb. prodr.* 46.
Branches flowering at the top round tubercles, tubercles bristled, flowers sessile, segments ovate cusp-acuminate smooth at the edge.

25. Stapelia caudata. *Tailed Stapelia.*
Lin. spec. ed. Willd. 1. 1286. *Thunb. prodr.* 46.
Stem rough-haired leafy, peduncles shorter than the corolla drooping, segments of the corolla linear acute.

26. Stapelia articulata. *Jointed Stapelia.*
Lin. spec. ed. Willd. 1. 1287. *Ait. kew.* 1. 310. *Masson monogr.* 20. *n.* 30. *t.* 30.
Branches flowering at the top round tubercles, tubercles mucronate, flowers subsessile, corollas papillose, segments lanceolate.

27. Stapelia mammillaris. *Prickly Stapelia.*
Lin. syst. 260. *Reich.* 1. 614. *Willd.* 1. 1287. *mant.* 216. *Thunb. prodr.* 46. *Burm. afr.* 27. *t.* 11.
Branches flowering in the middle erect hexagonal tubercled, tubercles spiny, peduncles shorter than the corolla, which is smooth with the segments lanceolate.

28. Stapelia pruinosa. *Frosted Stapelia.*
Lin. spec. ed. Willd. 1. 1287. *Masson monogr.* 24. *n.* 41. *t.* 41.
Branches erect four-cornered flowering in the middle, peduncles shorter than the flower, corollas pubescent, segments ovate acute.

29. Stapelia ramosa. *Branched Stapelia.*
Lin. spec. ed. Willd. 1. 1288. *Masson monogr.* 21. *n.* 32. *t.* 32.
Branches almost upright four-cornered flowering in the middle on the outside of the teeth, peduncles shorter than the flower, corollas flat, segments lanceolate rolled back at the edge.

30. Stapelia pulla. *Black-flowered Stapelia.*
Lin. spec. ed. Willd. 1. 1288. *Masson monogr.* 21. *n.* 31. *t.* 31.
S. fasciculata. *Thunb. prodr.* 46 ?
Branches erect subhexagonal flowering in the middle on the outside of the teeth, peduncles shorter than the flower, segments of the corolla erect lanceolate-acuminate rolled back at the edge.

31. Stapelia adscendens.
Lin. spec. ed. Willd. 1. 1288. *Roxb. corom.* 1. 28. *t.* 30.
Stem four cornered ascending flowering at the top, peduncles shorter than the corolla, which is smooth with the segments linear reflexed at the edge and acute.

32. Stapelia quadrangula.
Lin. spec. ed. Willd. 1. 1289. *Forsk. descr.* 52. *t.* 6.
Stem four-cornered, branches divaricating flowering at the top, teeth truncate, flowers sessile.

33. Stapelia incarnata. *Flesh-coloured Stapelia.*
Lin. syst. 260. *Willd.* 1. 1289. *suppl.* 171. *Thunb. prodr.* 46. *Masson monogr.* 22. *n.* 34. *t.* 34. *Burm. afr.* 15. *t.* 7. *f.* 1. (Euphorbium.)
Branches four-cornered stiff flowering at the top on the outside of the teeth, peduncles shorter than the corolla, the segments of which are lanceolate and acute.

34. Stapelia punctata. *Dotted Stapelia.*
Lin. spec. ed. Willd. 1. 1289. *Masson monogr.* 18. *n.* 24. *t.* 24.
Branches decumbent oblong somewhat four-cornered flowering in the middle, peduncles twice as long as the corolla, which is bell-shaped with the segments spreading lanceolate acute.

35. Stapelia geminata.
Lin. spec. ed. Willd. 1. 1290. *Masson monogr.* 18. *n.* 25. *t.* 25.
Branches decumbent round flowering at the top, peduncles geminate length of the corolla, the segments of which are lanceolate rolled back at the edge.

36. Stapelia decora.
Lin. spec. ed. Willd. 1. 1290. *Masson monogr.* 19. *n.* 26. *t.* 26.
Branches oblong decumbent round obscurely four-cornered flowering at the base, peduncles longer than the flower, bottom of the corolla five-cornered, segments ovate-lanceolate rolled back at the edge.

37. Stapelia pulchella.
Lin. spec. ed. Willd. 1. 1290. *Masson monogr.* 22. *n.* 36. *t.* 36.
Branches four-cornered decumbent flowering above the base, peduncles many-flowered, bottom of the corolla circular, segments ovate acute.

38. Stapelia vetula.
Lin. spec. ed. Willd. 1. 1291. *Masson monogr.* 15. *n.* 16. *t.* 16.
Branches four-cornered erect flowering at the base, peduncles shorter than the corolla, which is smooth, with the segments ovate acuminate three-nerved above.

39. Stapelia verrucosa.
Lin. spec. ed. Willd. 1. 1291. *Masson monogr.* 11. *n.* 8. *t.* 8.
Branches ascending four-cornered flowering at the base, peduncles longer than the corolla, which is warted, with the segments ovate and acute, and the bottom five-cornered and rugged.

40. Stapelia irrorata.
Lin. spec. ed. Willd. 1. 1291. *Masson monogr.* 12. *n.* 9. *t.* 9.
Branches from erect spreading four-cornered flowering at the base, peduncles longer than the corolla, which is wrinkled, with ovate acuminate segments.

41. Stapelia mixta.
Lin. spec. ed. Willd. 1. 1292. *Masson monogr.* 23. *n.* 38. *t.* 38.
Branches four-cornered ascending flowering at the base, peduncles length of the corolla, which is wrinkled, with a circular raised papillose bottom, and ovate acuminate segments.]

42. Stapelia variegata. *Variegated Stapelia.*
Lin. spec. 316. *Reich.* 1. 614. *Willd.* 1. 1292. *vir. cliff.* 20. *hort. cliff.* 77. *upsal.* 53. *Jacqu. misc.*

Fritillaria craſſa promont. bonæ ſpei. *Stap. theophr.* 335.

Branches four-cornered aſcending flowering at the baſe, peduncles longer than the corolla, which is wrinkled, with a circular concave wrinkled bottom, and ovate acute ſegments.

3. *Corolla ten-toothed.*

[43. Stapelia campanulata. *Bell-ſhaped Stapelia.*
Lin. ſpec. ed. Willd. 1. 1293. *Maſſon monogr.* 11. *n.* 6. *t.* 6.

Branches erect four-cornered flowering at the baſe, peduncles three-flowered, ſegments of the corolla larger lanceolate, with a bell-ſhaped bottom.

44. Stapelia barbata.
Lin. ſpec. ed. Willd. 1. 1293. *Maſſon monogr.* 11. *n.* 7. *t.* 7.

Branches moſtly four-cornered erect flowering at the baſe, peduncles ſhorter than the corolla, which is bell-ſhaped with the ſegments larger lanceolate acuminate rugged clubbed and bearded.

45. Stapelia venuſta.
Lin. ſpec. ed. Willd. 1. 1294. *Maſſon monogr.* 10. *n.* 3. *t.* 3.

Stem four or five-cornered erect branched at top, branches flowering at the baſe, peduncles longer than the corolla bent down, corolla ſmooth, ſegments larger ovate-acuminate, bottom concave ſurrounded by an elevated ring.

46. Stapelia guttata.
Lin. ſpec. ed. Willd. 1. 1294. *Maſſon monogr.* 10. *n.* 4. *t.* 4.

Branches ſomewhat ſpreading and four-cornered flowering at the baſe, peduncles length of the corolla, the ſegments of which are larger ovate acute, the bottom concave rugged ſurrounded by an elevated ring.

47. Stapelia humilis.
Lin. ſpec. ed. Willd. 1. 1294. *Maſſon monogr.* 10. *n.* 5. *t.* 5.

Branches four-cornered ſpreading flowering at the baſe, peduncles ſolitary ſhorter than the corolla, the ſegments of which are larger lanceolate acute.

48. Stapelia reticulata. *Netted Stapelia.*
Lin. ſpec. ed. Willd. 1. 1295. *Maſſon monogr.* 9. *n.* 2. *t.* 2.

Branches five-cornered ſpreading flowering at the baſe, peduncles in pairs ſhorter than the corolla, the ſegments of which are larger ovate acute, the bottom bearded ſurrounded by an elevated ring.

4. *Uncertain, the flowers being not yet known.*

49. Stapelia clavata. *Club-ſhaped Stapelia.*
Lin. ſpec. ed. Willd. 1. 1295. *Patterſon voy.*

Stem ſimple thick club-ſhaped nettedly and obſcurely warted, fruiting at the top.

DESCRIPTIONS, *&c.*

We have a remarkable inſtance in this ſingular genus how much may be accompliſhed by the induſtry of one man. Only two ſpecies of Stapelia were known to Linneus when he publiſhed his Species Plantarum in 1762; and there are no more than five in Murray's edition of the Syſtema Vegetabilium of 1784. Thunberg in his Prodomus (1794) has eight ſpecies. But Maſſon, in his beautiful monogram upon this genus has deſcribed and figured forty-one ſpecies, to which if we add the *hirſuta* and *variegata* long ſince known; two ſpecies diſcovered by Forſkahl in Arabia Felix; two by Thunberg not mentioned in Maſſon's work; one in the ſplendid work on Eaſt India plants now publiſhing by the Eaſt India Company; and one diſcovered by Colonel Gordon and Captain Paterſon at the Cape of Good Hope; we ſhall have the forty-nine ſpecies recited above. The laſt gentlemen found ſeveral others, but for want of complete figures and deſcriptions they cannot be ſufficiently characterized to be inſerted here. Forſkahl diſcovered five new ſpecies in Arabia Felix, of which two only that he figured well are in our catalogue. Father Loureiro has given two ſpecies, one native of China, the other of Cochinchina. He ſuſpects that it may be the ſame with the *carnoſa*. Ample as the harveſt has been, many probably yet remain undiſcovered. Mr. Maſſon is certain that the Cape countries contain ſeveral that he had not an opportunity of procuring. The whole genus ſeems peculiar to deſerts. Moſt of them are natives of the ſouthern promontory of Africa. The *hirſuta* has been found alſo by Monſ. Desfontaines near Kerwan in the kingdom of Tunis. Several are natives of Arabia Felix, and one of the Eaſt Indies, as mentioned above.

The deſerts between the ridges of mountains above the Cape of Good Hope are furniſhed with a great variety of theſe and other ſucculent plants, which, ſays Mr. Maſſon, are endowed by nature, as the camel is, with the power of retaining within them water, ſufficient to enable them to ſurvive the long periods of drought which prevail in thoſe regions. The climate there differs very much from that of the Cape itſelf, where the vegetable productions approach more to the nature of Alpine plants.

In the diſtribution of this genus I have followed Willdenow, and have given his ſpecific characters.

1. This is diſtinguiſhed from all the other ſpecies by its procumbent branched rooting ſtem, ſquarroſe toothlets of the leaves, and the corolla (which is of the ſame ſize as in *hirſuta*) being deeply five-cleft, and of a uniform yellow colour [i].

Branchlets erect, ſmooth, an inch long, grooved; the angles toothletted and tubercled; the toothlets ſpreading, acute. Flowers lateral on the branchlets, erect, large, ſolitary. Peduncle round, erect, ſmooth, one-flowered. Calyx five-leaved: leaflets lanceolate, acute, ſmooth. Corolla wheel-ſhaped, on the outſide ſmooth and purple, within aſh-coloured, papilloſe, rugged, the papillæ ruſeſcent at the tip; ſegments ovate, acute, with ſubclavate, ſpreading, ſnow-white ciliæ at the edge. Corolla the ſize of *S. variegata*.

Native of ſouthern Africa, below Boekland Berg; flowering in november and december [k].

2. Branches a foot high, glaucous, with the angles acute and toothed; the teeth ſpreading, remote, in the younger ones acute. Peduncles ſeemingly ſolitary, one-flowered, from the upper part of the branch, round, ſmooth, three lines long. Calyx five-parted; the parts ovate, acute, ſmooth. Corolla even, five-cleft beyond the middle: ſegments ovate, acute, revolute, ciliate at the edge with very fine club-ſhaped hairs: tube ſhort: genitals exſert [l]. Toothlets of the ſtem ſtraight, ſo that it appears as if it were repand. Corolla a little ſmaller than that of the preceding, of a uniform pale violet colour [m].

Native of ſouthern Africa in dry fields under ſhrubs, in the deſert beyond Oliſant's river: flowering in ſeptember and october [n].

3. Root compoſed of many ſtrong fibres, from which ariſe ſeveral ſtalks, which ſend out other branches of the ſame ſhape from their ſide, having indentures at each angle their whole length, the points of which are erect. Stalks or branches deep green, but the angles and points of the indentures inclining to brown, eſpecially if the plants be expoſed to the open air in ſummer. The flowers come out from the ſide of the ſtalks upon long fleſhy peduncles. Petal of a thick leathery ſubſtance; the inſide variegated and hairy, and the borders of the ſegments cloſely furniſhed with long brown hairs. In the centre is the double ſtarry nectarium, the points of which are lacerated; it covers the genitals and is of a purple colour. The outſide of the petal is of an herbaceous pale colour and ſmooth [o].

The corolla is yellow with tranſverſe ſtreaks of a dark violet colour; the ſegments violet at the end and along the edge; the bottom pale red, with red nectaries [p].

Native of the Cape of Good Hope. Introduced in 1714, by Profeſſor Richard Bradley. It flowers in june and july [q].

[i] Willdenow. [k] Maſſon. [l] Idem. [m] Willdenow [n] Maſſon. [o] Mill. fig. [p] Willdenow. [q] Hort. kew.

Digitized by Google

4. Plant a foot high, branched, purple: branches and branchlets thick: teeth at the angles remote, acute, curved in. Peduncles moſtly ſolitary, from the younger branchlets, three inches long, nodding, brown, turning purple. Calyx deeply five-parted; parts linear, acute. Corolla dark-purple with tranſverſe yellow wrinkles. It differs from *birſuta* in its whole habit; in having the branches divaricating, deeply five-cornered and ſomewhat reclining, the flowers nodding, and the corolla of one colour [s].

Willdenow remarks, that it reſembles the two next ſpecies in colour, but that it is ſufficiently diſtinct in the peduncle and ſtem. The bottom, centre or eye of the corolla is redder and very villoſe.

Native of the Cape of Good Hope. Maſſon cultivated it there, and it flowered in 1792. He introduced it at Kew, where it alſo flowered in 1797.

5. Plant a foot and half high. Branches club-ſhaped, pubeſcent, teeth at the angles remote and curved in, terminated by a very ſoft ſpinule. Peduncles often three-flowered, from the lower part of the branchlets. Calyx five-parted: parts lanceolate, acute. Corolla large, flat, dark-purple: ſegments towards the end ſmooth, with a tranſverſe wrinkle; the edge is fringed with long diſtich gray hairs [t].

Willdenow remarks that the centre of the corolla and the ends of the ſegments are of a darker colour than the reſt.

Native of ſouthern Africa in hot places, as at Sondags Rivier. It flowered in Maſſon's garden at the Cape in 1792.

6. Plant a foot and half high or more, pubeſcent. Teeth at the angles of the branches curved in. Peduncles three or four-flowered, from the lower part of the branches. Bracte at the baſe of the pedicel. Calyx five-parted: parts lanceolate, acute. Corolla large, flat: ſegments five-nerved, fringed with diſtich hairs [u].

It is ſufficiently diſtinct from the ſpecies moſt nearly allied to it by its many-flowered peduncles. The corolla, which is of the ſame ſize as in *birſuta*, is hiſpid, of a dark red purple colour, variegated with ſhort tranſverſe wrinkles of an almoſt black purple, and having the edge of the ſegments of a dark violet colour [x].

Native of ſouthern Africa in dry deſerts. It flowered in Maſſon's garden at the Cape in march 1794.

7. Plant a ſpan high. Branches and branchlets many, reclining, rooting; teeth ſuberect. Peduncles moſtly ſolitary, round, from the axils of the branches. Corolla large, flat, with the middle raiſed and extremely villoſe; ſegments ſpreading very much, oblong-rounded, ciliate. Before it flowers, the corolla is inflated and five-nerved, concave towards the end of the ſegments. The colour is very dark purple, with whitiſh wrinkles [y].

It is diſtinct from all the other ſpecies in the form of the corolla. The nectaries are very dark violet [z].

Native of ſouthern Africa; at Camies Berg among ſhrubs. It is called by the inhabitants *Arabiſch Roſe*; and flowered in Maſſon's garden at the Cape in 1792 [a].

8. Branches many, a ſpan and more in height, with ſmall erect teeth, a little curved in with a point. Peduncles often ſolitary, from the younger branchlets, round, pubeſcent, two inches long. Calyx five-parted: parts linear, acute. Corolla large, purple with pale yellow tranſverſe bands, deeply five-cleft, wrinkled, ſpreading: ſegments lanceolate, oblique, ciliate: tube none [b].

The nectaries or ſtar in the middle are white; the bottom is very dark purple [c].

Native of the deſerts of ſouthern Africa. It flowered in Maſſon's garden at the Cape in 1792.

9. Plant a ſpan high: branches many, ſmooth, with ſuberect teeth terminated by a ſpinule. Peduncles two or three, from the axil of the teeth, round, ſmooth, two inches long. Calyx five-parted, with the ſegments lanceolate, acute. Corolla large, dark, flat, tubercled, rugged: ſegments ovate-lanceolate. There is a variety, in which the corolla has golden dots ſcattered over it [d].

The corolla is of a duſky purple colour or almoſt black, with ſmall tranſverſe ſtripes of a paler hue; the bottom is very dark ſtudded with minute yellow dots. It is ſufficiently diſtinct from all the other ſpecies in having the ſegments of the corolla five-nerved above, and the outſide of it yellow dotted with purple, whereas in the reſt it is almoſt always pale and of one colour [e].

Native of ſouthern Africa, in dry places among ſhrubs beyond Platte Kloof. It flowered in the royal garden at Kew in 1796 [f].

10. Branches and branchlets a ſpan long, very ſmooth, with remote ſmall blunt teeth. Peduncles one to three, from the younger branches, round, ſmooth, an inch long. Calyx five-parted: ſegments linear, acute. Corolla very ſmooth, ſhining: ſegments ſpreading: fleſh-coloured [g]: double the ſize of Borage flowers, with orange-coloured nectaries [h].

Native of ſouthern Africa. It flowered in Maſſon's garden at the Cape in 1792.

11. Plant a hand high, rufous. Teeth at the angles of the branches erect, obtuſe. Peduncles commonly two or three, ſhort, round, purple. Calyx five-parted: ſegments linear, acute. Segments of the corolla triangular, colour rufous [i]: the ſize of *Periploca græca* or a little larger, of a dark violet colour variegated with tranſverſe ſtreaks of a very dark purple, with the bottom ſtellate and of a uniform rufous colour. Nectaries variegated [k].

Native of ſouthern Africa, in hot places beyond Platte Kloof. It flowered in Maſſon's garden at the Cape in 1793.

12. Plant a hand high. Branches many, ſmooth, ſuberect, toothed. Peduncles four or five, ſhort, round, ſmooth. Calyx five-parted, with ovate acute ſegments. Corolla flat, ſmooth, aſh-coloured, very dark purple towards the ends of the ſegments, which are narrow, tailed and very ſharp-pointed [l].—The corolla is a little larger than in the preceding, variegated with dark-purple tranſverſe waved ſtreaks, very finely fringed with white at the edge [m].

Native of ſouthern Africa, in Namaqualand. It flowered in Maſſon's garden at the Cape in 1791.

13. Plant a hand high and ſmooth. Branches cluſtered, reclining; with ſpreading, acute teeth. Peduncles moſtly ſolitary, ſeldom branched, round, ſmooth, an inch long, from the younger branchlets. Calyx five-parted: parts lanceolate-acute. Corolla dark-purple, with the middle recurved, and the ſegments ſpreading, wheel-ſhaped, folded back, fringed at the edge [n].

Corolla the ſame ſize as in *S. rufa*, uniformly dark-purple, with yellow nectaries. It is diſtinct from the two preceding ſpecies in having the branches ſpreading and reclining, with larger teeth; the corolla of one colour, with lanceolate ſegments, and the bottom raiſed by an impreſſion from without, and longer peduncles [o].

Native of ſouthern Africa.

14. This is a low plant: branches abundant, cluſtered, ſmooth, preſſed to the ground, rooting, with recurved acute teeth. Peduncles two or three, from the lower branchlets, half an inch long. Calyx five-parted: ſegments triangular, acute. Corolla five-cornered, ſlightly recurved, dark-purple: ſegments triangular, acute, hiſpid, folded back and fringed at the edge [p].

Corolla leſs than that of the preceding, very dark violet with a rufeſcent bottom; and yellow nectaries [q].

Native of ſouthern Africa.

15. This is a dwarf plant: branches numerous, cluſtered, ſmooth; with ſpreading acute teeth. Peduncles two or three, from the lower part of the branchlets, round, ſmooth, purple, three lines long. Calyx five-parted: parts lanceolate, acute. Corolla

five-

Digitized by Google

five-cornered, recurved in the middle: ſegments ſpreading, narrowed, folded back and ciliate. Colour dark-purple [*]. Size nearly that of the preceding; with the bottom circular, greeniſh, and the nectaries yellow [p].

Native of ſouthern Africa under ſhrubs. It flowered in Maſſon's garden at the Cape in 1793.

16. Plant a hand high. Teeth of the branches ſpreading, acute. Peduncles erect, ſolitary, on the upper part of the branches. Calyx five-parted: parts lanceolate, acute. Corolla ſmall, yellowiſh-white: ſegments ovate-lanceolate, flat, dotted, ſetaceous towards the tip [q].—The ſize as in Aſclepias Vincetoxicum, pale yellow dotted at the baſe, hairy and ſubciliate at the tip, with a yellow bottom, and whitiſh nectaries [r].

Native of ſouthern Africa, in Kanna Land. Found by Maſſon in 1792.

17. Plant a foot high, ſmooth, upright, branched: teeth recurved. Peduncles on the upper part of the branches, two ſeldom three, nodding. Calyx five-parted: parts ſmall, acute. Corolla ſmall: ſegments linear-lanceolate, wrinkled, flat, ſpreading. Colour of the plant purpliſh; of the corolla greeniſh-yellow [s].

Flowers the leaſt in this genus, the ſize of Cynanchum erectum, dotted with purple, very finely ciliate. Nectaries orange-coloured. Peduncles not from the axils of the teeth, but from a callus between them: incarnata and ramoſa flower in the ſame manner [t].

Native of ſouthern Africa, in Namaqua Land.

18. Flower of the ſame ſize as in S. arida. Segments of the corolla beſet at the tip with hairs all directed one way.—Native of Arabia Felix [u].

19. Plant a hand high and very ſmooth: branches and branchlets toothed; teeth erect, acute. Peduncles commonly two, from the lower part of the branchlets, round, ſmooth, purple, an inch long. Calyx five-parted: ſegments linear, acute. Corolla flat, aſh-coloured with whitiſh briſtles: ſegments ovate-lanceolate, wrinkled, hiſpid [x].—Size of Anemone nemoroſa, aſh-coloured with tranſverſe brown ſtreaks and covered with white briſtles; bottom of a uniform brown colour [y].

Native of ſouthern Africa. It flowered in Maſſon's garden at the Cape in 1794.

20. Plant a ſpan high: branches many, almoſt upright, toothed, acute. Peduncles two or three, axillary, two inches long, round, purpliſh. Calyx five-parted: parts linear, acute, rough-haired. Corolla flat: ſegments ovate-lanceolate, ſpreading, having blood-red dots ſcattered over them, and being covered with club-ſhaped hyaline hairs: colour ſulphureous [z]. Size the ſame as in the preceding: nectaries orange and black [a].

Native of ſouthern Africa, in the deſerts about Nord Oliſant's Rivier. It flowered in Kew garden, october 1796 [b].

21. Plant a hand high, very ſmooth, glaucous. Branches divaricating, obſcurely toothed; teeth very blunt. Peduncles four or five, in bundles from the lower part of the branchlets, round, ſmooth, twice as long as the branches. Calyx five-parted, acute. Segments of the corolla obſcurely wrinkled; fringed at the angles, dotted with gray beneath, rolled back at the edge. Colour purpliſh-brown, varying to yellow [c].

This ſpecies is very diſtinct from the reſt, in the length of the peduncle, and the ſtructure of the flower and branches. The peduncles are five inches long. The corolla is the ſize of Cineraria lanata: the baſe is aſh-coloured dotted with brown, and has a bundle of pedicelled glands; the bottom is blackiſh [d].

Native of ſouthern Africa in Camies Berg. It flowered in Maſſon's garden at the Cape in 1792.

22. Plant half a hand high, ſmooth, glaucous. Branches many, divaricating, with very blunt teeth. Peduncles ſolitary? Corolla flat: ſegments wrinkled, five-nerved [e]. It reſembles the preceding in the peduncle and branches, but the flower is very different. Branches obſcurely toothed, obtuſely three or two-toothed at the tip. Peduncles three inches long and more, ſpreading. Corolla of a dirty duſky purple, wrinkled with very ſhort darker ſtains: bottom circular, aſh-coloured dotted with black. The flower is ſmaller than in the preceding [f].

Native of ſouthern Africa, in Namaqua Land, near Kok Fontein [g].

23. Branches thick, erect, ſet with tubercles which have a ſpine in the middle. Corolla one of the largeſt in this genus, being near three inches in diameter, repand and five-toothed, with wide very ſhort roundiſh very ſhortly acuminate teeth. Colour yellowiſh brown with a whitiſh centre, and black nectaries. It differs abundantly from all the other ſpecies in the ſingular form of the corolla, inſomuch that it might be doubted whether it belongs to this genus.

Native of the Cape of Good Hope in Groot Namaqua Land toward Orange Rivier [h]. Maſſon had this ſpecies from Gordon.

24. Plant a ſpan high or more. Branches erect, round, grooved, tubercled: tubercle briſtly. Flowers ſolitary, between the tubercles, on the upper part of the branches. Calyx five-parted: parts lanceolate, acute. Corolla dark-purple, with a ſmall, raiſed, red circle in the middle, ſurrounding the genitals.

Native of ſouthern Africa, on very dry hills, under ſhrubs; as below Roggeveldt Bergen. It is eaten by the Hottentots, who call it Guaap [i].

25. Native of ſouthern Africa, where it was found by Thunberg.

26. This is a low ferruginous plant. Branches purpliſh, divaricating, oblong, netted: net hexagonal, convex: ſpinules of the teeth minute. Peduncles ſolitary. Flowers at the top of the branches, dark-coloured: ſegments triangular, papilloſe above [k].

Corolla the ſame ſize as in *pilifera*. The branches are not unlike the female ſpikes of Zea Mays [l].

Native of ſouthern Africa at Roggeveldt. The Hottentots eat the ſtalks raw, and the Dutch pickled with vinegar [m]. Introduced in 1774, by Maſſon [n].

27. Flower ſmall. Suſpected by Maſſon to be the ſame with the *articulata*, but it appears from Burman's figure, and ſeveral marks to be different [o]. Introduced in 1774 by Maſſon [p].

28. Plant a foot and half high, purpliſh: branches almoſt erect, with recurved teeth. Flowers from the upper part of the younger branches, dark-purple with white hairs. Peduncles two or three, ſhort, round. Calyx five-parted: parts ovate, acute. Corolla ſmall: ſegments flat, covered with very ſmall white hairs, as if with a hoar froſt. The ſame ſize as in *S. pilifera*.

Native of ſouthern Africa, in Namaqua Land among ſhrubs. It flowered in the Kew garden, in june 1797 [q].

29. Plant a foot high or more, extremely branched and very ſmooth: angles of the branches very bluntly toothed. Flowers aggregate on the upper part of the branchlets, on ſhort peduncles. Calyx five-parted: parts ſmall, acute. Corolla dark-purple [r]: ſize of the preceding, with the bottom circular, whitiſh. The flower proceeds from a callus on the outſide of the teeth [s].

Native of ſouthern Africa, beyond Platt Kloof, near the hot baths. It flowered in Maſſon's garden at the Cape in auguſt 1792.

30. Plant a ſpan high. Teeth at the angles of the branches ſpreading, prickly. Flowers aggregate, three or four, on very ſhort peduncles. Calyx five-parted: parts ſmall, acute. Corolla dark-purple, deeply five-cleft [t].

Diſtinct from the preceding by its hexagonal acuminate-toothed branches, and flowers a little larger, growing on the outſide of the teeth but not placed on a callus, with the ſegments erect [u].

Native of ſouthern Africa, in hot ſandy places in the deſert. It flowered in march, in Maſſon's paſſage from the Cape to St. Helena [x]. He introduced

it in 1774 at Kew, and it flowered there in auguſt and ſeptember [r].

31. Stems ſeveral, a foot or two high, at the baſe reſting on the ground and ſtriking root; above erect, with blunt notched angles. Branches erect like the ſtems. Leaves alternate, ſeſſile, on the angles of the branches, lanceolate, very minute. Flowers axillary, about the extremities of the branches, generally ſingle, erect, ſmall, variegated with dark purple and yellow. Calyx five-cleft to the bottom: diviſions lanceolate. Corolla tube ſcarcely any: border flat. Follicles erect, as thick as a gooſe quill, four or five inches long.

This plant is not very common in the Eaſt Indies, of which it is a native: it grows among buſhes, on high dry barren ground; flowering during the wet ſeaſon. The natives eat the moſt ſucculent tender branches raw, although they are bitter and ſalt to the taſte [z].

Willdenow remarks, that the flower is of the ſame ſize with that of *Periploca græca*; yellow with violet tips.—The Telingas name it *Car-allum*.

32. Angles of the ſtem ſomewhat toothed. It is of a duſky green, a foot and half high and branched; the ſides half an inch wide. Flowers cluſtered, ſmall, terminating, yellowiſh-green. Calyx five-toothed, permanent. Follicles two inches, and often a ſpan long. Seeds downy. Juice not milky but watery.—Native of Arabia Felix [a].

33. Plant a foot high or more, ſmooth. Branches erect, with ſpreading, acute, callous teeth at the angles. Flowers ſubſeſſile, moſtly ſolitary at the ends of the branches. Calyx five-parted: parts lanceolate acute. Corolla flat, ſmooth, fleſh-coloured varying to white [b].

The flowers are ſmall, (the ſize of *S. pilifera*.) The tender branches are eaten by the Hottentots [c].

Native of ſouthern Africa, in dry ſandy fields.

34. This is a procumbent plant: joints oblong, ſmooth, with ſharp teeth thickened at the baſe. Peduncles three or four, from the axils of the teeth, an inch and half long, round, ſmooth, purpliſh. Calyx five-parted: ſegments lanceolate, acute, purple. Corolla whitiſh, with blood-red dots [d]. Size as in *S. rufa*.

Native of ſouthern Africa, in Namaqua Lands. It flowered in Maſſon's garden at the Cape in 1790.

35. This is a low plant: branches very abundant, preſſed to the ground and rooting, oblong, ſomewhat four-cornered, ſmooth, having ſmall ſharp teeth. Peduncles in pairs, round, ſmooth. Calyx five-parted: parts lanceolate, acute. Corolla orange-coloured with blood-red dots: diviſions narrow, ſpreading, glandular [e]. The ſize of the preceding; from which it differs, in not having the bottom of the corolla bell-ſhaped, in the peduncles being geminate not aggregate, and the branches round with four rows of very minute diſtant toothlets [f].

Native of ſouthern Africa, in hot places under ſhrubs. It flowered in Maſſon's garden at the Cape, in february 1794.

36. Branches many, ſmooth, compoſed of oblong roundiſh joints, with ſmall acute teeth. Peduncles two, round, ſmooth, purple. Calyx five-parted: parts lanceolate, acute. Corolla yellow mixed with black, narrowed, lanceolate, ſpreading, rugged above, rolled back at the edge. Perhaps a variety of the preceding [g]: from which however it differs in having ſmaller joints, ſtouter teeth, and the corolla a little bigger, rugged with dark-purple dots [h].

Native of ſouthern Africa. It flowered in Maſſon's garden at the Cape in 1794.

37. This is a ſmooth branching plant: branches and branchlets reclining, with acute and ſomewhat ſpreading teeth. Peduncles from the axils of the branchlets, reclining. Calyx five-parted, lanceolate, acute. Corolla an inch in diameter, pale with blood-red dots: ſegments triangular, acute, dotted: a ſmall ring ſurrounds the genitals [i].

Corolla the ſame ſize as in *S. concinna*. The ſegments at the tip and the circular bottom are browniſh [k].

[r] Hort. kew. [z] Roxburgh. [a] Forſk. in Willdenow.
[b] Maſſon. [c] Linn ſuppl. [d] Maſſon. [e] Idem.
[f] Willdenow. [g] Maſſon. [h] Willdenow. [i] Maſſon.
[k] Willdenow.

Native of ſouthern Africa. It flowered in Maſſon's garden at the Cape of Good Hope in 1793.

38. Plant a hand high, very much branched, ſmooth. Teeth of the branches erect, curved in at the top. Peduncles two or three, from the lower part of the branches; the younger ones round and ſmooth. Calyx five-parted: parts lanceolate, acute. Corolla dark-purple, flat, deeply five-cleft, ſmooth: ſegments lanceolate, obtuſe, three-nerved; with wrinkled tranſverſe bands: tube none [l]. Size rather leſs than that of *S. variegata*, (n. 42.) deep violet, with ſhort tranſverſe very dark violet bands, and a very dark purple bottom: but it is ſufficiently diſtinguiſhed by the ſegments being three-nerved above [m].

Native of ſouthern Africa on mountains: Hex River.

39. Branches many, cluſtered, ſuberect, toothed: branchlets decumbent: toothlets of the branches decuſſated, acute, ſomewhat ſpreading. Peduncles one or two, from the lower part of the branchlets, an inch long, round, ſmooth. Calyx ſmall, five-parted: parts ovate, acute. Corolla flat, warted, pale yellow with blood-red dots, a little raiſed into a pentagon form in the middle, and there rugged and ſurrounding the genitals [n]. Size of *S. variegata*, at the ends of the ſegments and round the bottom browniſh [o].

Native of ſouthern Africa, in dry places; flowering in ſeptember and october.

40. Branches many, a hand high, cluſtered, toothed, ſmooth, ſuberect; branchlets decumbent; toothlets of the branches acute, ſomewhat ſpreading, decuſſated. Peduncles often ſolitary, round, ſmooth, an inch long. Calyx ſmall, five-parted: parts ovate, acute. Corolla large, flat, pale yellow with blood-red dots, without any ring [p].

It differs from the preceding in having no warts or pentagon ring to the corolla; the branches from upright ſpreading; and the colour of the corolla ſulphureous with bloody dots and a blood-red bottom [q].

Native of ſouthern Africa, in dry places; flowering in ſeptember and october.

41. Branches many, diffuſed, reclining, rooting, teeth ſubrecurved, acute. Peduncles moſtly ſolitary: nodding, three inches long, purpliſh. Corolla large, ſmooth, purple with tranſverſe yellow wrinkles: ring yellow, with purpliſh papillæ [r].

It is ſo like the next ſpecies that it might be taken for a variety; but it differs in the form of the toothlets on the branches, in the ſize of the flower which is double of that, with the ſegments acuminate, and a raiſed papilloſe centre, in the colour and eſpecially the form of the nectary. The corolla is duſky violet wrinkled with tranſverſe yellow ſtreaks; the bottom yellow with red papillæ [s].

Native of ſouthern Africa. It flowered in Kew garden in 1796 [t].]

42. Branches many, the ſize of a man's finger, four or five inches long, having ſeveral protuberant indentures on their ſides which ſpread open horizontally, and ending in acute points; theſe branches ſpread on the ground and emit roots from their joints; they are angular, and of a deep green colour in ſummer, but in winter change to purpliſh; they abound with a viſcous juice of a nauſeous taſte. From the ſide of the branches towards the bottom comes out the peduncle, at one of the ſinuſes; it is ſhort, and ſuſtains one flower. Corolla large and thick, cut half way, and ſpreading open flat; greeniſh on the outſide, but yellow within, having a circle of purple round the nectaries, which are prominent and of a livid colour: the whole corolla is finely ſpotted with purple, reſembling the belly of a frog. The flower when blown has a very fetid odour like that of carrion; ſo that the common fleſh fly depoſits its eggs on it, which frequently are hatched; but wanting proper food, die ſoon after. After the flowers are paſt, the double germ changes into four taper pods (follicles) joined at their baſe, near a ſpan long, and almoſt as thick as a man's finger.

[l] Maſſon. [m] Willdenow. [n] Maſſon. [o] Willdenow.

Digitized by Google

[Corolla ſulphur-coloured, with tranſverſe wrinkles, variegated with duſky purple irregular ſpots, and a paler circular bottom. It differs from *verrucoſa* and *vetula*, in its wrinkled corolla, circular bottom, and the whole habit [u].

Native of ſouthern Africa, on rocks, into the crevices of which it ſtrikes the fibres of its roots. Introduced in 1690, by Mr. Bentick. It flowers in june and july [x].

43. Branches many, erect, four-cornered, or ſometimes, but rarely, five-cornered, clouded with purple: teeth ſpreading, acute. Peduncles from the lower part of the branchlets, branched: branches two or three, one-flowered. Calyx five-parted to the baſe; ſegments lanceolate, acute. Corolla bell-ſhaped, without a ring, ten-cleft, five of the diviſions longer, five ſhorter, ſpreading: tube bearded within, with club-ſhaped hairs. Colour ſulphureous, the whole ſurface having rugged raiſed purple dots ſcattered over it. Genitals in the bottom of the tube [y].

It is ſufficiently diſtinct from the following ſpecies; the corolla being ſpotted not only within, but on the outſide alſo; the bottom bell-ſhaped; and the peduncles many-flowered [z].

Native of ſouthern Africa.

44. Branches many, cluſtered, ſmooth, four or five-cornered: toothlets ſomewhat ſpreading, acute. Peduncles moſtly three, from the lower part of the branchlets, purple, three lines long, one-flowered. Calyx five-parted: parts linear-lanceolate, acute. Corolla bell-ſhaped, without a ring, rugged within, bearded with club-ſhaped hairs, whitiſh with rugged purple dots ſcattered over it: five ſegments ſhorter, acute, five longer, almoſt tailed, ſomewhat ſpreading. Genitals in the bottom of the corolla [a].

Corolla bell-ſhaped, with the ſegments ſpreading, not with the bottom only bell-ſhaped, and the border flat, of a whitiſh yellow colour, with raiſed dark-purple dots, and club-ſhaped hairs [b].

Native of ſouthern Africa. It flowered in Maſſon's garden at the Cape, in march 1794.

45. Branches a ſpan long, ſmooth, quadrangular or ſometimes but ſeldom quinquangular: branchlets divaricating: toothlets of the branches ſpreading, acute. Peduncles commonly two in the axils of the teeth, round, ſmooth, an inch long, pendulous, one-flowered. Calyx five-parted: parts ovate, acute. Corolla large, ſulphur-coloured with blood-red dots; with five ſegments longer, and five ſhorter ſpreading, a little acute: tube ſmooth, gradually widening into a ring. Genitals in the bottom of the tube [c].

This differs from the reſt in having the ſtem erect, branched at top, and the peduncles hanging down [d].

Native of ſouthern Africa; in Karro.

46. Branches many, cluſtered, four-cornered, (the younger ones often five-cornered,) a hand long, ſmooth: toothlets acute, ſpreading. Peduncles three or four, from the lower part of the branchlets, one-flowered, divaricating, bracted at the baſe. Calyx five-parted: parts linear, lanceolate, acute. Corolla ſulphur-coloured with blood-red dots: five of the ſegments longer five ſhorter acute ſpreading: tube rugged within, bell-ſhaped, gradually widening into a ring [e].

The figure of the corolla as in the preceding, but the bottom rugged: the ſtem alſo is different [f].

Native of ſouthern Africa.

A new ſpecies is figured in Mr. Curtis's magazine, (t. 506.) which in the ſhape and colour of the corolla agrees very well with this; but the flowers in that ſit on longer peduncles, which ariſe from the baſe of the ſtalk, the ſtalks are undivided, and the tubercles are not hooked. It is named *Stapelia lentiginoſa* or Freckled Stapelia. It was introduced into the royal garden at Kew by Mr. Maſſon, and flowered in the collection of E. D. Woodford, Eſq. at Vauxhall, in 1801.—The ſtems are branched at top; the branches are five-cornered, ſpreading, and tubercled, the tubercles hooked. The corollas are ten-toothed, with the ſegments alternate and indiſtinct, the bottom concave girt with a raiſed ring.

47. Branches many, half a hand high, almoſt upright, four or five-cornered; branchlets ſpreading: teeth of the branches ſpreading, acute. Peduncles ſolitary, three lines long, round, ſmooth, one-flowered. Calyx five-parted: parts linear-lanceolate, acute. Corolla about an inch wide: five of the ſegments longer, five ſhorter acute ſpreading: tube bell-ſhaped, widening into a ring; which is of a dark purple colour with white waved ſpots; ſegments ſulphur-coloured with purple dots. Genitals in the bottom of the tube [g].

It differs from the other ten-toothed ſpecies, in the ſhortneſs of the ſtem, the ſmallneſs of the flower, and the peduncles being invariably ſingle [h].

Native of ſouthern Africa.

48. Branches many, cluſtered, clouded with purple: angles acute, with acute very ſpreading or recurved teeth. Peduncles two or three, round, ſmooth, one-flowered. Bractes three or four, at the baſe of the peduncles. Calyx five-parted: parts linear, acute. Corolla ten-angled: five of the angles ſhorter, five longer, ſpreading a little, acute: tube bell-ſhaped, bearded within, gradually widening into a raiſed ring. Colour of the corolla dark-purple, with white lines like the meſhes of a net. Genitals in the bottom of the tube.

Native of ſouthern Africa, in hollows of rocks towards Olifant's Rivier; flowering in ſpring and autumn [i].

49. This ſpecies is yet obſcure, the fruit only having been figured by Captain Paterſon.

Native of ſouthern Africa, in ſandy fields beyond Kopper-berg [k].]

PROPAGATION AND CULTURE.

They are propagated here very eaſily during the ſummer months, by taking off any of the ſide branches, which, when planted, put out roots very freely. The branches ſhould be ſlipped off from the plants to the bottom, where being joined by a ſmall ligature, they will not occaſion a great wound, the joints at the place where they are connected being almoſt cloſed round; for if they are cut through the branch, the wound will be ſo great as to occaſion their rotting when planted: theſe ſhould be laid in a dry place under cover for eight or ten days, that the wounded part may dry and heal over, otherwiſe they will rot; then they ſhould be planted in pots filled with freſh ſandy earth, mixed with lime rubbiſh and ſea ſand; and if the pots are plunged into a very moderate hot-bed, it will promote their taking root; they ſhould be now and then ſprinkled with water, but it muſt be given them ſparingly; and as ſoon as they have taken root, they muſt be inured to the open air. If theſe plants are kept in a very moderate ſtove in winter, and in ſummer placed in an airy glaſs-caſe, where they may enjoy much free air, but be ſcreened from wet and cold, they will thrive and flower very well; for although they will live in the open air in ſummer, and may be kept through the winter in a good green-houſe, yet thoſe plants will not flower ſo well as thoſe managed in the other way. They muſt have little water given them, eſpecially in winter.

The *birſuta* and *variegata* only were cultivated in Mr. Miller's time, but the reſt are to be increaſed and treated in the ſame manner. In upwards of forty years that Mr. Miller cultivated the *variegata*, he never ſaw it produce pods but three times; and that was when the plants were plunged into the tan-bed in the ſtove, into which the branches had put out long roots, and thereby became very luxuriant. Of the *birſuta* he never ſaw any pods produced in England.

Claſſ. 5. 3. Pentandria Trigynia.
Nat. order of *Tribilatæ*. *Rhamni*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* five-parted, concave, roundiſh, coloured, almoſt as big as the corolla.

COR. *Petals* five, oblong, erect, like the calyx.
Nectary from the receptacle of the fructification, in the bottom of the flower, concave, pitcher-ſhaped.

STAM. *Filaments* five, oblong, erect, length of the calyx. *Anthers* ſimple.

PIST. *Germ* thickiſh, three-parted. *Styles* three, ſimple, much longer than the ſtamens. *Stigmas* obtuſe, contiguous.

PER. *Capſules* three, inflated, flaccid, united longitudinally by a ſuture, opening inwards by the acuminate apexes.

SEEDS two, bony, globular, with an oblique point and an orbicular excavation by the ſide of the apex.

OBS. *The ternary number of the piſtil and pericarp, in* S. pinnata *becomes binary.*

ESSENTIAL CHARACTER.

Cal. five-parted. *Pet.* five. *Capſ.* inflated, connate. *Seeds* two, globular with a wart.

Leaves ternate, ſtyles and capſules three.

DESCRIPTIONS, &c.

[1. This is a tree from twenty to thirty feet high, with a ſmooth unarmed trunk, and round, ſmoothiſh, ſhining branches. Leaves petioled, alternate: pinnas two or three pairs with an odd one, petioled, ovate, acuminate, ſerrate, ſmooth, ſhining: petioles both general and partial roundiſh, ſmooth. Stipules in pairs between the pinnas, minute, curved in. Panicles terminating, erect, looſiſh; with oppoſite decuſſated branches, and three-flowered pedicels. Flowers white odorous. Calyx five-leaved; the two inner leaflets the ſize of the petals. Capſule the ſize of a Cherry, ſmooth not inflated, three-celled.

Native of Jamaica; flowering there in ſpring and autumn [1].]

2. This has ſeveral ſhrubby ſtalks ariſing from the ſame root, and growing ten or twelve feet high, covered with a ſmooth bark, and dividing into ſeveral branches, which are ſoft and pithy. The leaves are compoſed of two pairs of ovate leaflets terminated by an odd one: theſe differ greatly in ſize, according to the ſtrength and vigour of the ſhrubs; ſome being more than two inches long, and an inch and half broad; but on old weak ſhrubs they are much ſmaller: they are ſmooth, entire, and of a light-green colour, ſtanding upon pretty long foot-ſtalks. The flowers come out upon long ſlender pendulous peduncles, from the axils of the ſtalks near their extremity, in oblong bunches. The petals are white, and expand in form of a Roſe. The flowers appear in may, and are ſucceeded by inflated capſules, compoſed of three cells, one or two of which have a roundiſh, ſmooth, hard ſeed, and the other is barren. [Leers ſays, that the ſtyles are ſometimes two, but moſtly three; that the capſule is three-celled; and that the ſeeds are conſtantly two in the larger cells, that in the third being abortive. According to Smith, the capſules are two, very ſeldom three, membranaceous, ventricoſe, commonly two-ſeeded. Seeds globular, brown, ſhining, hard.

Gærtner deſcribes the capſule as compoſed of two joined together, ovate, twin, membranaceous, inflated, veined, two-celled, opening inwards by its acuminate apexes. Receptacle a thick nerve in the middle of the partition, putting forth on each ſide very ſhort umbilical chords nearly oppoſite, changing when ripe into broad umbilical fungous areas. Seeds fix to ten in each cell, of which one or two only ripen; theſe are ſubglobular, bony, very ſmooth, ſhining, browniſh-yellow, contracted towards the baſe, and ending in an oblique point; but there truncate as it were, and marked with a wide umbilical area.

It is a low branching ſmooth ſhrub, ſomewhat like a dwarf Aſh. Leaves alternate: leaflets ovate, (or varying to lanceolate, but always pointed,) ſerrulate. Racemes terminating, compound, nodding. Bractes briſtle-ſhaped, membranaceous. Flowers bell-ſhaped, whitiſh, or yellowiſh-white [m].

Native of the South of Europe. It is found in England, in hedges, but is ſcarcely indigenous with us. Gerarde ſays that in his time it grew at the houſe of Sir Walter Culpepper, near Flinmewell in the Weald of Kent, as alſo in the Fryer-yard without St. Paul's gate in Stamford, and about Spalding Abbey, and in the garden of the Right Hon. the Lord Treaſurer his very good lord and maſter, and by his houſe in the Strand. Alſo in his own garden, and in the garden hedges of Sir Francis Carew, near Croydon.—Parkinſon ſays, it groweth in many places of this land, as at Aſhford in Kent, and at Milton near Cambridge. According to Ray, it is found in hedges about Pontefract in Yorkſhire, but ſcarcely in ſufficient plenty to be deemed certainly wild.]

Mr. Miller affirms, that it is found in woods in ſeveral parts of England.

It is cultivated as a flowering-ſhrub, and makes a variety, when intermixed with others, though the flowers are not very beautiful. The nuts being hard and ſmooth are ſtrung for beads by the Roman Catholics in ſome countries; and the children of the poor inhabitants eat the nuts, though they have a diſagreeable taſte.

3. This has a more ſubſtantial ſtem than the preceding, the bark of the old branches and ſtalks is ſmooth and of a gray colour; that of the young ones is of a light green and very ſmooth. The leaflets are ovate, ending in a point, and ſerrate on the edges: the largeſt three inches long and two broad; but in old plants they are not much more than half the ſize. The flowers are produced from the ſide of the branches in longer bunches than thoſe of the former ſort, but their peduncles are much ſhorter; the flowers are of a clearer white, and their petals are ſomewhat larger; as are alſo the bladder capſules: the ſeeds are larger, and ripen better.

Native of North America; and now as common in the nurſery-gardens as the other ſort. [It was introduced before 1640, by Mr. John Tradeſcant, ſenior [n].]

[1] Swartz.

[m] Smith. [n] Hort. kew. from Parkinſon.

PROPA-

Digitized by Google

PROPAGATION AND CULTURE.

2, 3. Both theſe ſorts are uſually propagated by ſuckers from the root, which the ſecond ſends out in plenty; theſe ſhould be taken from the old plants in autumn, and their roots trimmed, then planted in a nurſery, in rows at three feet diſtance, and one foot aſunder in the rows; in this nurſery the plants ſhould ſtand one or two years according to their ſtrength, and then be tranſplanted to the places where they are to remain.

The plants which are propagated in this manner from ſuckers, are more ſubject to put out ſuckers in greater plenty from their roots, than thoſe which are raiſed from ſeeds, or propagated by layers or cuttings, ſo are not to be choſen when the others can be had; therefore thoſe who propagate them for their own uſe, ſhould prefer the other methods. If they are propagated by layers, the young branches ſhould be laid down in autumn, in the ſame manner as is practiſed for other trees and ſhrubs; theſe will have put out roots the following autumn, when they may be taken from the old plants and planted in a nurſery, where they may grow one or two years to get ſtrength, and then may be removed to the places where they are to ſtand.

When theſe are propagated by cuttings, it ſhould be the ſhoots of the former year, and if they have a ſmall piece of the two years wood at the bottom, they will more certainly ſucceed; for as the young ſhoots are ſoft and pithy, ſo they are very ſubject to rot, when they have no part of the old wood to them. They ſhould be planted in autumn on a ſhady border, but muſt not have too much wet.

They may alſo be propagated by ſowing their ſeeds early in autumn, in beds of light freſh earth; and when the plants are come up, they muſt be carefully kept clear from weeds, and in very dry weather, if they are now and then refreſhed with water, it will greatly promote their growth; in theſe beds they may remain until october following; at which time they ſhould be carefully taken up and planted in a nurſery, placing them in rows three feet aſunder, and the plants one foot diſtance in the rows; and, if the following ſpring ſhould prove very dry, it will be convenient to give them a little water to encourage their taking root; after which they will require no farther care but to keep the ground clear from weeds in ſummer, and every ſpring to prune off irregular branches, and dig the ground between the rows to looſen the earth, that their roots may the more eaſily extend. In this nurſery they may remain two years, by which time it will be proper to tranſplant them out where they are to remain, either in wilderneſs quarters, or in clumps of various trees, where they will add to the diverſity. The beſt ſeaſon for tranſplanting theſe trees is in autumn, with other deciduous trees. When theſe ſeeds are ſown in the ſpring, the plants ſeldom come up till the following year.

GENERIC CHARACTER.

CAL. *Perianth common* of a different ſtructure in the ſeveral ſpecies.

Perianth proper one-leafed, funnel-form: *tube* narrowed: *border* entire, plaited, ſcarioſe.

COR. funnel-form. *Petals* five, united at the baſe, narrowed below, above wider, obtuſe, ſpreading.

STAM. *Filaments* five, awl-ſhaped, ſhorter than the corolla, inſerted into the corolla by their claws. *Anthers* incumbent.

PIST. *Germ* very minute. *Styles* five, filiform, diſtant. *Stigmas* acute.

PER. *Capſule* oblong, ſomewhat cylindrical, membranaceous, five-cuſped, one-celled, valveleſs.—*Proper calyx* contracted at the neck, expanded in the border, cheriſhing the capſule when the corolla withers.

SEED ſingle, oblong, hanging from a long cord.

OBS. Statice *of authors with the common calyx threefold, compoſes a roundiſh flower.*

Limonium *of authors with the common calyx imbricate exhibits florets in an oblong row.*

S. monopetala *ought not to be diſtinguiſhed generically, ſince in the other ſpecies which are pentapetalous the filaments are inſerted into the very claws of the petals.*

ESSENTIAL CHARACTER.

Cal. one-petalled, entire, plaited, ſcarioſe. *Pet.* five. *Seed* one, ſuperior.

Leaves radical ſpatulate obtuſe glaucous quite entire on long petioles, ſcape round, branches panicled, flowers racemed, directed one way.

DESCRIPTIONS, *&c.*

1. Common Thrift has a perennial woody root, bearing many thick tufts of lax, linear, channelled, ſmooth, entire leaves. Scapes erect, ſimple, pubeſcent, varying much in height (from two to eight inches or even a foot,) terminated by a globular head of many flowers, encompaſſed by a many-leaved involucre, the baſe of which is attached to a ſingular cylindrical membranous ſheath, about an inch long, and inveſting the top of the ſcape, its lower end being looſe and lacerated, ſo that it ſeems to have been torn off from the root, and carried up with the young growing ſtem. Calyx ſmall, erect. Corolla roſe-coloured or pink, (varying to deep red, ſcarlet and white.) Petals obovate, clawed. Crown of the ſeed fringed.

Native of Europe and North America. Common in England, Wales and Scotland, both on the ſea ſhores and on the higheſt mountains. Its favourite maritime ſoil is in the mud or ouze. It grows well in gardens, even within the ſmoke of London, and probably derives its Engliſh name from its readineſs to thrive in any ſituation. It flowers from june to auguſt *.]

Mr. Miller makes three ſpecies of this, two growing on the Alps and other mountains, and the third in ſalt marſhes. The firſt, which he names *Statice Armeria* or great mountain Pink, has the leaves about four inches long, and half an inch broad in the wideſt part. The ſcapes are about a foot high; and the flowers are pale red, varying to white: they appear in june.

The ſecond, which is alſo a native of mountains, ſeldom riſes more than two inches high, but when planted in gardens, becomes much larger. The leaves are narrow, and three-cornered at the baſe. The ſcapes are about ſix inches high; and the corollas are of a pale purpliſh colour, appearing in may, and continuing the greater part of june.

There is a variety of this with bright red flowers, commonly called Scarlet Thrift. The flowers make a much better appearance than thoſe of the other.

This, which Mr. Miller names *Statice montana*, or ſmaller mountain Thrift, was formerly in great eſteem for edgings on the ſides of borders in flower-gardens. But it requires to be tranſplanted every year, to keep it within due bounds; and where a plant fails, as is frequently the caſe, it leaves a large unſightly gap.

* Smith brit. & engl. bot.

Digitized by Google

The third ſort, which he names *Statice maritima*, or leaſt Sea Pink; and grows naturally in ſalt marſhes, where the ſea flows over it frequently, has very narrow, ſhort, flat leaves, the ſcapes ſeldom riſe more than three or four inches high; the heads of flowers are ſmall, and of a pale fleſh colour. It flowers later in the ſeaſon than either of the former.

[2. Tufted, ſmooth. Leaves half an inch long, with a white dagger point. Scape twice as high as the leaves, ſtriated. Head, flowers, &c. as in St. Armeria. If it be a variety of that, it is certainly a remarkable one; retaining its habit after being cultivated ſeveral years in a garden; and not having been remarked any where on the coaſt of the Mediterranean except in Spain and Portugal [p].

3. This is very like the firſt ſpecies, but the leaves are twice the width, ſhorter, acute, and narrowed at the baſe.—Native of Spain, on the mountains of Enguera, and at the foot of the mountain Montduber and Oroſpeda [q].

4. Leaves broad-lanceolate, ſometimes elliptic, ſmooth, quite entire, nerved, for the moſt part mucronate, on a channelled petiole ſheathing at the baſe. Scape round, ſtriated, erect. Sheath reflexed, membranaceous, toothed at bottom, involving the ſcape at top. Bractes ſcarioſe, oblong, obtuſe. Calyx membranaceous, funnel-ſhaped. Petals roſe-coloured, obtuſe [r].]

This ſeems to be the ſpecies, which Mr. Miller ſays was ſome years paſt in the Engliſh gardens, and came from Portugal. He deſcribes the ſtalk as thick and perennial, becoming ſhrubby by age, and riſing to a foot and half in height; the leaves like thoſe of the the firſt ſort, but much larger; the ſcapes a foot and half long, terminated by one large globular head of flowers, of a pale red colour. All the plants in England were deſtroyed by the ſevere froſt in the beginning of the year 1740. [It was introduced again in 1775, by Joſ. Nich. de Jacquin, M.D.; and is a native of Algarbia [s] in Portugal: alſo of Spain, about Cadiz, &c. Desfontaines found it in ſands near La Calle in Barbary.

5. This was introduced in 1780, by Mr. William Malcolm, but from what place is unknown. It flowers in june and july [t].

6. Sea Lavender, as it is commonly called, though it has ſcarcely any reſemblance to Lavender, and none of its aromatic quality, has a ſtrong, perennial, woody root. This plant varies much as to luxuriance, being ſometimes found with leaves ſcarcely an inch long, and not more than ſix or eight flowers in a panicle, and at other times much larger, with the flowers far more abundant. The bright blue colour diſtinguiſhes it at a diſtance, and that colour is tolerably permanent. Though leſs magnificent than ſome of the foreign ſpecies, it is a beautiful plant [u]. The leaves are obovate-lanceolate and quite entire. The ſcape is alternately branched, with the branchlets corymbed [x]. Capſule covered by the calyx and corolla, oblong, roundiſh, membranaceous, five-cuſped at the top. Seed ſmooth, ſomewhat of a ruſt colour [y].]

Mr. Miller ſeparates the Limoniums from the Statice; and makes three ſpecies of this. 1. Our common Sea-Lavender, (Limonium vulgare, which grows in ſalt-marſhes in ſeveral parts of England: the roots of which are thick, of a reddiſh colour, and an aſtringent taſte, ſending out many ſtrong fibres, which ſtrike deep in the ground: from the upper part of this come out ſeveral ſmooth ſtiff leaves, of a pretty thick conſiſtence, and a dark or glaucous green, from four to five inches long, and more than two inches broad in the middle. Stalks naked, more than a foot high, dividing into many branches, which are ſubdivided into others ſmaller towards the top; the latter are terminated by ſlender ſpikes of pale blue flowers, ranged on one ſide the ſtalk above each other, coming out of narrow covers like ſheaths. Theſe appear in july; and are ſucceeded by oblong ſeeds, incloſed in the calyx, and ripening in autumn.

[p] Vahl. [q] Willdenow. [r] Desfontaines. [s] Hort. kew. [t] Idem. [u] Engl. bot. [x] Smith brit. [y] Gærtner.

2. L. narbonenſe, or large late-flowering Sea Lavender of Narbonne; growing naturally on the ſea coaſt of the South of France. The leaves are ſix inches long, and three broad. The ſtalk riſes fifteen or ſixteen inches high. It ſeldom flowers till the end of auguſt, and never produces any good ſeeds in England.

3. L. humile, or ſmalleſt Engliſh Sea-Lavender, (n. 4.) Leaves lanceolate, about three inches long, and an inch broad in the middle, leſſening gradually to both ends. Stalk four or five inches high, dividing into many ſpreading branches, which are very thick ſet with ſhort ſpikes of whitiſh-blue flowers. Theſe appear in auguſt, and the ſeeds ripen in october.

[In Dillenius's edition of Ray's ſynopſis, three Engliſh ſpecies of Limonium or Sea Lavender are diſtinguiſhed. 1. The common ſort, which is larger in ſalt marſhes, ſmaller on cliffs and in the fiſſures of rocks. 2. L. minus, obſerved in England by Plukenet; near Harwich by Doody, and near Ramſgate by Dale. Doody, who obſerved it in flower in the royal garden at St. James's, ſays it differs not only in its ſmallneſs, but in having the leaf decurrent along the petiole to the very root. 3. Smaller Sea Lavender, with more branching ſtalks, and flowers more thinly ſet. The leaves are longer and more pointed, and it flowers later. Dale found it on the ſea banks by the tide mill at Walton in Eſſex, and between Heybridge and Maldon. Mr. Sherard and Mr. Rand found it at the mouth of the river that runs from Chicheſter.

Both varieties are on the Lancaſhire coaſt at Low Furneſs, and on the weſt ſide of Milnthorpe ſands in Weſtmoreland. *Mr. Gough* [z].

Mr. Woodward remarks, that there are two varieties on the Suffolk coaſt, much ſmaller than the common, and which differ in having no regular footſtalk, but only a continuation of the leaf: the one has the leaves ſhort and blunt, the other has them longer and more pointed. The ſharp point at the end of the leaf marks them as belonging to this ſpecies [a].

7. This reſembles the preceding very much, but the leaves are firmer, and not plaited and waved about the edge; their obovate form, the more diſtant point, the flowers only half the ſize and more cluſtered, and the different habit of the whole ſcape, proclaim this to be a diſtinct ſpecies.

Native of Siberia, in ſalt places from the Jaick to Angara.

8. Very like the next ſpecies but not hairy; leaves ſmaller; and the ſcapes almoſt as in St. Limonium. The margin of the leaves appears to be crenate, but on a nicer inſpection it is very fine waved. The lower ſurface is covered with ſmall raiſed dots, viſible only with a magnifier. The trivial name was given it by Pallas from the uſe to which the ſcapes are applied.—Native of Siberia [b].

9. Leaves all radical, oblong, a foot or more in length, entire, ſlightly waved, ſometimes emarginate, pubeſcent and ſoft to the touch, being ſprinkled all over with little ſtellated bundles of ſoft ſhort hairs. Stalks very much branched, and ſpreading in every direction, covered with the ſame kind of pubeſcence as the leaves, but rather more harſh; branches roundiſh, alternate, terminating in ſimple horizontal racemes. Bractes ſmall, concave, acute, two together at each diviſion of the panicle, one of which is placed on the outſide of the branch at its baſe, and the other in its axil. Flowers moſtly two together, emerging from two ſmall bractes, like thoſe on the ſtalk; but furniſhed alſo with two larger and more obtuſe bractes, with a large membranous margin. Calyx tubular, membranous, five-toothed, whitiſh with five green angles. Corolla longer than the calyx, blue. Anthers yellow.

Firſt gathered by Gerber in Ruſſian Tartary, on the banks of the river Don, near Aſoph. It flowered in the Duke of Northumberland's garden at Sion in 1788. Communicated by Mr. Hoy his Grace's gardener [c].

10. Root perennial, woody. Leaves radical, entire, flat, running down into the petiole, margined,

[z] Withering. [a] MSS. [b] Willdenow. [c] Smith in Linn. tranſ.

acuminate

Digitized by Google

acuminate with a ſmall ſtiffiſh point. Stems tough, upright, dichotomous, ſomewhat flexuoſe, round, ſmooth, naked or having a ſingle leaf near the baſe. Flowers on the extreme branches in cloſe ſpikes, all on one ſide upwards, three together; the middle one flowering firſt, next one of thoſe on the ſide, and then the other. A bracte under each ſide flower. Calyx funnel-ſhaped, membranaceous above the middle, permanent, five-cleft; clefts ovate; greeniſh at the baſe, and rayed with five raiſed reddiſh lines. Corolla red, conſiſting of five petals, but cohering ſo as to appear to be one-petalled: the claws ſeem as it were connate into a tube longer than the calyx; but the borders are ovate and emarginate. The ſtamens do not riſe above the corolla. Anthers ſagittate, yelloviſh with a white pollen. Styles briſtle-ſhaped, white, longer than the calyx. Seed brown, ſtriated, ſubovate, covered with the baſe of the dry corolla.—Raiſed from ſeeds ſent by Profeſſor Allione of Turin[d].]

This has ſmall, oval, obtuſe leaves about two inches long and an inch broad, of a lighter green than the common Limonium, on pretty long foot-ſtalks, which are bordered or winged with a membrane which runs cloſe to and partly embraces the upper part of the root. The ſtalk riſes a foot and half high, ſending out branches alternately on each ſide; the lower ones are long, and the others gradually diminiſh to the top, forming a looſe kind of pyramid; they all point upwards, and towards their ends ſend out ſpikes of pale-blue flowers, which are erect. It flowers late in auguſt, and never perfects ſeeds in England. It grows naturally in Narbonne and Provence. [Italy and Spain. Cultivated by Mr. Miller in 1759. Willdenow warns us not to confound it with the reticulata.

11. Root perennial. Leaves radical elliptic-lanceolate, three-nerved, hoary, ſomewhat waved, mucronate at the point. Scape round, with triangular branches. Calyx white, ſurrounded with five acute green ſtreaks; and having three or four, awl-ſhaped, ſpreading, ſhort bractes. Flowers white[e]. Vahl deſcribes the bractes as ovate-acuminate, embracing, and membranous at the edge; with four glumes which are oblong, acuminate, unequal, concave, ſpreading at the top, membranous at the edge, the inmoſt trifid: ſegments linear, acute.—Native of Egypt and Siberia.

12. Leaves all radical, thick, nerveleſs, terminated by a rigid point, half an inch long. Scape erect, even, a ſpan high. Branches none but ſimple peduncles, round, ſpreading, lateral and terminating. Spikes ſolitary or ſometimes two together, oblong, peduncled, ſpreading. Flowers very much cluſtered, directed one way, erect, in a double row, four incloſed in as many bractes. Bractes unequal: two outer ſhorter, ovate; two inner larger, all of a browniſh glaucous colour, with a membranaceous ſhining margin and a marginal purpliſh line. Beſides there are two very tender bractes at the baſe of each floret.—Native of the coaſt of Barbary.

Brouſſonet ſent another plant gathered in Spain, with wider ſhorter leaves, the ſcape a finger's length, and faſtigiate peduncles, but ſcarcely differing ſpecifically from this. It differs from the *cordata*, which has the leaves rounded at the tip or retuſe without a point, the ſcape branched, the ſpikes alternate, erect, round, many on one common peduncle, the flowers alternate, ſolitary within the ſcales. It is allied to Scopoli's *oleæfolia*, but different[f].

13. Leaves wedge-ſhaped, emarginate at the end, and ſometimes quite entire, rigid, running down into the petiole. Leaves varying in ſize, according to the ſoil[g].

Leaves ſpatulate, ſcarcely retuſe. Flowers numerous, blue, imbricate, one-ranked[h].]

Leaves many thick fleſhy ſpatulate ſmooth grayiſh, growing next the root and ſpreading on the ground. Stalks naked about ſix inches high, dividing towards the top into many ſmaller branches, which are terminated by ſhort crooked panicles of ſmall pale-red flowers. Theſe appear in auguſt, but never produce ſeeds in this country. It grows naturally near the ſea, about Marſeilles, Leghorn, [the maritime rocks of Piedmont, Spain, &c. and in Barbary.—It was cultivated in 1752, by Mr. Miller[i].

14. 15. Natives of the Cape of Good Hope, where they were found by Thunberg[k].

16. Root ſtrong, woody and perennial, bearing thick tufts of ſmall narrow obovate ſpatulate or wedge-ſhaped leaves, ſlightly pointed but not awned, and entire. Scapes proſtrate, very much branched; the branches flexuoſe, matted and entangled with each other, having an ovate ſharp membranous bracte at each divarication: many of the branches are barren, and thoſe often reflexed, but not always. Flowers few together in ſimple terminating ſpikes or bundles, erect, each enveloped in three or four larger blunt bractes. The ribs of the calyx, and the petals, are of a bright purpliſh blue, which turns white in drying[l].

Native of the South of France and Malta. Wheeler obſerved it in Greece. It is alſo found on the Eaſt coaſt of England, particularly in Norfolk, where it covers many acres of muddy ſalt-marſhes with its blue flowers in july and auguſt, eſpecially about Wells, Cley and Holkham. Mr. Woodward obſerved it abundant about Wells; Meſſrs. Crowe and Pitchford at Blakeney, Wells, Cley and Brancaſter; Mr. Sutton at Holme by the ſea. Mr. Hemſted found it below Wiſbeach, and Mr. Skimſhire in Tydd marſh, Cambridgeſhire.] Mr. Miller, in the ſeventh edition of his Dictionary, 1759, ſays it was found on the coaſt of Norfolk by Mr. Scott, a gardener, now (1759) reſiding at Weybridge in Surry; and in the eighth edition (1768) he adds, that it has been ſince found in plenty in Lincolnſhire, by Joſeph Banks, Eſq. [now the Right Hon. Sir Joſeph Banks.—Hill, in his Flora Britanica (1780) ſays that it was found near Wells in Norfolk by Dr. Watſon, afterwards Sir William Watſon. In the firſt edition of Hudſon's Flora Anglica (1762) it is ſaid to grow on our ſea coaſts, but without mention of any particular place.

Dr. Smith remarks, that Plukenet's figure moſt reſembles S. echioides; and that Boccone's is too imperfect to be of any ſervice.

β. Root woody. Leaves all radical, imbricate-patulous, ſpatulate, quite entire. Stem a foot and half high, flexuoſe, round, leafleſs; branches alternate, with a ſcale at the baſe of each, which is embracing, ſhort, acute: theſe are ſubdivided, and are many times dichotomous: the lower ſterile, the upper flowering in corymbs. Flowers in ſeveral rows, oblong, ſubimbricate, one-ranked, erect. Calyx turbinate, with a white, ſcarioſe, five-cleft border. Corolla pale blue.

Native of Spain: abundant near the Convent of Santa Barbara, by Rivar, two miles from Madrid: flowering in june and july. It ſeems to be intermediate between the *reticulata* and *echioides*. The ſtem is upright in this, whereas in *reticulata* it is proſtrate: the leaves are ſpatulate, and not tubercled as in *echioides*; the petals alſo are united at the baſe[m].

According to Willdenow, this differs from the *reticulata* only in its ſmoothneſs, and in having the radical leaves larger.

The ſame author ſuſpects that the variety γ may be a diſtinct ſpecies. The leaves are linear-cuneiform ſharpiſh at the point; the flowers are larger and more diſtant.—It is a native of Siberia.

17. Leaves tongue-wedge-ſhaped, bluntiſh, not perfectly even. Panicle biſarious, jointed; joints divaricating, ſubtubercled: branchlets dichotomous. Calyxes ſmall, acute. Petals emarginate, pale blue with a purpliſh ſtreak[n].

Leaves radical, ſpreading in a roſe, obovate, tubercled, ſometimes ſpatulate, quite entire; on a broadiſh petiole. Scape ſlender, upright, branched at top. Branches filiform, panicled. Flowers diſtinct, ſolitary, ſeſſile, ſpreading, looſely racemed. Calyx thin, ſomewhat bowing, involved in an elongated, acute, tubercled bracte. Petals very narrow, ſcarcely longer than the calyx[o].]

It

Digitized by Google

It is an annual plant, (rather biennial) with long narrow leaves, which are ſet with rough tubercles, like thoſe of Viper's Bugloſs. Stalks about eight inches high, dividing into two or three ſmall branches, which are terminated by ſhort reflexed ſpikes of pale-blue flowers, coming out late in auguſt, and ſeldom perfecting ſeeds in England.

[Native of the South of Europe, and in Barbary near Maſcar, in the clefts of rocks. Cultivated in 1752, by Mr. Miller [b].

18. Radical leaves many, oblong, ſmooth, curled, ending in a ſharp point. Stems a foot high, branched, round, firmer than in the other ſpecies, ſometimes winged, three or four ſpreading round the bottom, where there is abundance of very elegant flowers which are larger than thoſe of the common Limonium and white, forming a handſome ſilvery head. The whole plant has a bitteriſh ſalt taſte [q].

Linneus remarks, that the root is biennial, and the calyxes undivided.

Native of Ruſſia. Introduced in 1776, by Chevalier Murray. It flowers in july and auguſt [r].]

19. Leaves about four inches long, and three quarters of an inch broad in the middle, diminiſhing gradually to both ends. The ſtalks riſe about five or ſix inches high, dividing into ſeveral ſpreading branches, which are again divided into ſmaller; theſe are terminated by ſpikes of pale-blue flowers ranged on one ſide the foot-ſtalk; the whole, when growing, being ſpread wide, has ſomewhat the appearance of an umbel of flowers. Theſe come out in auguſt, but never ripen ſeeds here. It was diſcovered by Tournefort in the Levant, whence he ſent the ſeeds to the royal garden at Paris.

[Native of Ruſſia. Cultivated by Mr. Miller in 1731. It flowers in june [s].

20. Leaves imbricate, flat above, rugged about the edge, mucronate-ſpiny at the end; the lower ones reflexed.—Native of Greece and the deſerts of Media.

21. Native of Siberia [t].

22. Leaves radical, obovate-lanceolate, even, petioled, obtuſe, with a terminating point: ſtem-leaves few. Scape almoſt naked, branched. Calyxes purpliſh, with five blood-red rays. Corollas purpliſh. It reſembles S. Limonium very much, but the leaves are blunter; the flowers are twice as large and coloured; and there are a few leaves on the ſcape above the root. Native of the Cape of Good Hope [u].

23. Native of the Cape of Good Hope.

24. Plant ſcarcely the length of a finger. Flowers pale red [x].

Stems ſhrubby, forming a cloſe tuft. Leaves very ſmall, obcordate, glaucous, rigid, perennial. Scape almoſt filiform, upright, branched. Flowers in a ſmall looſe panicle [y].—Native of the ſhores of the Mediterranean.

25. Native of the Canary iſlands, where it was found by Maſſon, and introduced in 1780. It flowers in ſeptember and october [z].

26. Native of Siberia, where it was found by Gmelin [a].—Introduced in 1781, by Meſſrs. Lee and Kennedy. It flowers moſt part of the ſummer [b].]

27. Stalk ſhrubby, about two feet high, dividing into ſeveral woody branches, which ſpread out on every ſide; the lower part of theſe are cloſely furniſhed with gray leaves, like thoſe of the Sea Purſlain, and of a thick conſiſtence. The branches are terminated by panicles of blue flowers, coming out ſingly at a diſtance from each other, having one funnel-ſhaped petal, with a long tube, and dividing into five ſpreading ſegments at top. It flowers from june till autumn, but never produces ſeeds in England.

Native of Sicily, where there is a variety which bears galls like thoſe upon the Oak; but the plants in England have no appearance of theſe.

[Leaves alternate, glaucous, rigid, rough, twiſted, perennial; with ſheathing petioles. Flowers axillary, ſolitary. Corolla one-petalled, five-cleft: tube incloſed in an obliquely truncate ſheath. The branches frequently bear galls.

Native of Barbary in wet ſand and ſalts near Kerwan [c]. Cultivated in 1732, by Mr. Miller [d].

28. Stem upright, round, covered with ſcales at bottom, branched. Leaves alternate, cluſtered, quite entire, obtuſe, ſmooth, thick, gradually leſſening to the baſe, an inch long, of the ſame form with thoſe of *St. monopetala*. Common peduncle round, longer than the leaves: pedicels flexuoſe, flattiſh on one ſide. Flowers minute. Glume four-valved: valves oblong, ſmooth, membranaceous and blunt at the edge. It has quite the ſame ſtructure as the preceding, but with an axillary infloreſcence.—Native of Arabia.

29. Stem upright, round, the thickneſs of a gooſe quill, covered all over with imbricate, ovate, obtuſe, dry ſcales. Leaves towards the ends of the branches, cluſtered, cylindrical, ſometimes a little curved in, placed on brown ſheathing ſcales, even, coriaceous and ſolid, very blunt, mucronate, unequal, often an inch long. Spikes panicled. Flowers cluſtered. Common peduncle from the uppermoſt axils, two or three inches long, flexuoſe. Glume three valved, involving the calyx: valves unequal, concave, membranous at the edge, ſhorter than the calyx: the inner ones oblong, the outer one roundiſh. Calyx ſmooth, whitiſh, with five brown rays [e].—Native of Arabia and northern Africa.

30. Found by Thunberg at the Cape of Good Hope.

31. Native of Dauria in mountainous paſtures.

32. Stems round, ſomewhat woody, naked with alternate chaffs, panicled. Branchlets very much ſubdivided, in bundles, filiform, imbricate with very minute chaffs, terminated by a little briſtle. Flowers ſubimbricate, aſcending, directed one way, yellow [f].—Native of Spain, Portugal and Barbary.

33. Branches alternate, ſhorter than the ſtem. Under each branch a lanceolate-ſubulate, ſmoother ſtipule. Branches like the ſtem, with two obtuſe jointed branchlets. Linneus had not ſeen the radical leaves, nor the fructification [g].

The ſtem and branches are jointed: the joints under the branches end in an oblong, brown, ſmooth ſcale, membranous at the edge. Branchlets from the axils of the branches, having a ſimilar ſcale at the baſe. Spikes panicled from the end of the branches [h]. Native of Paleſtine.]

34. This is a biennial plant. The lower leaves, which ſpread on the ground, are indented almoſt to the midrib; theſe indentures are alternate and blunt. The ſtalks riſe a foot and half high, dividing upwards into ſeveral branches, having at each joint three narrow leaves ſitting cloſe to the ſtalks, from whoſe baſe proceeds a leafy membrane or wing which runs along on both ſides the ſtalk; theſe are rough and a little hairy. The ſtalks are terminated by panicles of flowers, which ſit upon winged peduncles, each ſuſtaining three or four flowers of a light blue colour, which continue long without fading. It flowers in july and auguſt, but unleſs the ſummer is warm and dry, the ſeeds do not ripen in England.

[Root-leaves decumbent, hirſute, running down into the petiole, widening gradually from the baſe upwards, obtuſe, lyrate-ſinuate; with the lobe obtuſe, often reverſed: ſtem-leaves in threes, narrow-lanceolate. Stem upright, dichotomous, with four or five leafy, ſtiffiſh, ſubhirſute, and ſometimes toothed wings. Flowers glomerate, corymbed, terminating, ſeſſile, fenced with membranous, concave bractes, mucronate at the tip. Calyx funnel-form, with a blue, toothletted, widened border, reſembling a corolla. Petals five, pale yellow, ſhorter than the calyx, with an oblong blunt border [i].

This is one of thoſe few plants whoſe calyx is of a more beautiful colour than the corolla, which it does not loſe in drying. The flowers therefore, in a dried ſtate, are an ornament to the houſe in winter [k].

STA

Native of Sicily and the Levant. Cultivated by Mr. Miller in 1731[l].—But this ſingular ſpecies of Statice was long ſince an inhabitant of our gardens, for Parkinſon, in his Paradiſus ſays, "it hath been "ſent us out of Italy many years before either Guil-"laume Boel found it in Cales, or Cluſius in Ma-"lacca."

Since his time it appears to have been confined to few gardens: the nurſerymen have lately conſidered it as a newly-introduced ſpecies, and ſold it accordingly[m].

By what is ſaid above, it appears to be a native of Spain; and Desfontaines found it in Barbary, on ſandy coaſts.

β. Mr. Miller makes a diſtinct ſpecies of the ſame plant, or a variety of it, which comes from Africa. He deſcribes it as] a biennial plant, with the lower leaves few, ſpear-ſhaped, hairy, ſlightly ſerrate, about two inches long, and half an inch broad. The ſtalk riſes about fifteen inches high, and at each joint has three narrow leaves, ending in acute points; from the baſe of theſe leaves is continued a leafy membrane, running along the ſtalk on each ſide; theſe ſtalks branch out but little, and are terminated by ſhort panicles of flowers, the peduncles of which are not winged: each peduncle ſuſtains two or three flowers of a bright blue colour, out of the middle of which ariſes another ſmall flower of a pale yellow colour. It flowered in july and auguſt 1757, but did not ripen ſeeds. It was raiſed by Mr. Miller in Chelſea garden, from ſeeds which were brought him from Africa.

[γ. Another variety was found by Dr. Shaw in Africa, with the wings of the ſtems membranaceous entire, and the bractes obtuſe and ſmooth, not ſharp and hiſpid. In β the leaves are leſs ſinuate.—In α the ſtem and branches are round below and not winged[n].

35. The plant is ſmaller than the *ſinuata*, but the ſtems and branches are round. The bractes are like thoſe of the *ſinuata*. The calyxes are white, and the corollas blue.—Native of Africa[o].

36. Root tuberous. Calyx and petals whitiſh.—Native of Perſia[p].

37. Root perennial, branched, fibrous, fragrant. Stems a cubit high, branched, diffuſed, winged with leafy triple decurrent margins, interrupted at each joint, waved, curled, the ſame colour and ſubſtance with the leaf, triangular at the lower baſe, green. Branches axillary, alternate, ſolitary or many, ſpreading. Leaves alternate, ſpreading: the radical ones ovate-lanceolate acute larger: the ſtem-leaves ſpatulate or obovate, ſharply acuminate narrowed at the baſe into the petiole, entire or ſcarcely toothletted, waved, one-nerved, veinleſs, ſqualid with white atoms, glaucous-green, permanent, from twelve to fifteeen lines in length, and from ſix to nine in breadth. Petioles widiſh, half-embracing, channelled on one ſide, angular on the other, the length of the leaf. Panicle terminating, compoſed of ſpikes, diſtich, diffuſed, with leaves ſometimes intermixed, four or five inches long. Spikes alternate, peduncled, the lower ones at the apex of the extreme branchlets from the axil of the upper leaf, bracted, directed the ſame way, halved, reflexed. Flowers ſeſſile, two from each glume, directed one way, aſcending, very cloſe, purple. Bractes double to each flower, imbricate, erect: outer alternate, ſeſſile, ovate, acute, concave, obſcurely coloured, with membranous edges: inner or proper glume two-flowered, larger, two-leaved; the outmoſt roundiſh, emarginate, compreſſed, with a green diſk and membranous ſides; the inmoſt oppoſite, minute, linear, membranaceous, pellucid. It differs from *ſinuata* in having entire leaves, frondeſcent and very curled ſtems.

Native of Morocco.—In the time of Guy de la Broſſe, the firſt prefect of the Paris garden, it was cultivated there; and a beautiful figure of this very elegant plant is extant among his inedited plates. It has ſince been introduced again by Profeſſor Louis Guillaume Le Monnier from African ſeeds[q].—It was introduced at Kew in 1784, by Mr. Francis Maſſon[r].

38. Leaves radical ſpatulate or ſpatulate-lanceolate, quite entire, narrowed to both ends, running into the petiole. Scape erect, with ſpreading branches; and a ſmall ovate acute ſcalelet preſſed cloſe to the baſe of the branches. Flowers racemed, directed one way, from the apexes of the branchlets. Border of the calyx and petals white. The leaves vary in ſhape.—Native of Barbary, by hot ſprings near Bone.

39. Leaves radical, glaucous, hoary, ſpatulate, obtuſe, rigid, quite entire, erect, running into a long petiole. Scape erect, round, firm, panicle-branched at top. Flowers in racemes, directed one way, from the top of the branches.—Native of Barbary, on rocks near La Calle[s].]

PROPAGATION AND CULTURE.

1. Thrift may be propagated by parting the roots in autumn, that the plants may take good root before froſt comes on, and that they may flower ſtronger than if they were planted in the ſpring. If they are permitted to ſtand long unremoved, they are ſubject to rot and decay, eſpecially in good ground.

6. The common Sea Lavender, and moſt of the other ſorts, are abiding plants, and will thrive in the open air. The Engliſh ſorts may be eaſily procured from the places where they grow. They may all be tranſplanted at almoſt any time of the year, provided they are carefully taken up, preſerving ſome earth to their roots, and in hot weather ſhaded till they have taken new root; after which time they will require no other culture but to keep the ground clean from weeds, and in the ſpring to ſtir up the ground between them to looſen it. As theſe plants do not require much culture, or take up much room, a few of each ſort may be allowed to have a place in gardens, where there is room, for the ſake of variety. Theſe plants do not propagate very faſt in gardens, ſo the roots need not be removed oftener than every third or fourth year, at which time they may be ſlipped to increaſe them; the beſt time for this is in the autumn, that the plants may be well rooted before the ſpring, otherwiſe they will not flower very ſtrong the following ſummer. They ſhould be planted in a loamy ſoil, on an eaſt aſpected border, where they may enjoy the morning ſun, but ſcreened from the great heat in the middle of the day; in ſuch a ſituation the roots will continue ſeveral years, and flower as well as in their native ſoil.

Theſe plants may alſo be propagated by ſeeds, ſo that ſuch of them as do not grow naturally in England, may be obtained by procuring their ſeeds from abroad. Theſe ſhould be ſown upon a border expoſed to the morning ſun, and on a ſoft loamy ſoil, early in the ſpring, for the ſeeds lie a conſiderable time in the ground before the plants come up; therefore the ground muſt be kept entirely clean from weeds, and if the ſeaſon ſhould prove very dry, the border ſhould be watered two or three times a week, otherwiſe the ſeeds will lie a whole year before they vegetate; when the plants come up, they muſt be kept clean from weeds, and in very dry weather watered, and in the autumn they may be tranſplanted where they are deſigned to remain.

34. This and another ſpecies or two (17. 18.) are biennial plants, and rarely perfect their ſeeds in England, ſo that unleſs freſh ſeeds can be procured from warm countries, where they ripen well, it will be very difficult to continue the ſorts. If the ſeeds of theſe can be obtained time enough to ſow them in the autumn, the plants will come up the following ſpring; but when they are ſown in the ſpring, they ſeldom grow the ſame year. Theſe ſeeds ſhould be ſown on a border of loamy earth, not ſtiff or moiſt, and expoſed to the ſouth; but when the ſun is warm, the border ſhould be ſhaded with mats, to prevent the earth from drying too faſt. When the plants come up, they muſt be kept clean from weeds; and if they are too cloſe, ſome of them ſhould be carefully taken out as ſoon

as they are fit to remove, and planted in ſmall pots, placing them in the ſhade till they have taken new root; then they may be placed where they may enjoy the morning ſun till autumn, when they ſhould be put into a hot-bed frame, where they may be ſcreened from hard froſt, but enjoy the free air in mild weather; and thoſe plants which are left in the border where they were ſown, muſt be covered with mats in hard froſt; for though they will often live through the winter in mild ſeaſons, yet hard froſt will always deſtroy them. The following ſummer the plants will flower, and if the ſeaſon proves warm and dry, they will ripen ſeeds, and the roots ſoon after decay.

[The common practice in treating *Statice* Limonium, is to conſider it as a greenhouſe plant; and indeed it appears to the greateſt advantage in a pot; it is much diſpoſed to throw up new flowering-ſtems; hence by having ſeveral pots of it, ſome plants will be in flower throughout the ſummer. On this account, and for the ſingularity of its large blue calyx, it is a plant that merits attention. Though in a manner a biennial, it may be often increaſed by parting its roots. It ſometimes produces ſeeds in England, but ſparingly [t]. The *echioides* (n. 17.) is alſo a greenhouſe plant: but the *ſpecioſa* is ſufficiently hardy.]

25. 26. 27. Statice pectinata, ſuffruticoſa, and monopetala are ſhrubby plants, which are too tender to live through the winter in the open air in England, ſo the plants muſt be removed into ſhelter in the autumn, but they only require protection from hard froſt: theſe plants may be placed with Myrtles, Oleanders, and other hardy green-houſe plants, where they often continue to flower great part of winter, and make a pretty variety. Theſe ſorts are eaſily propagated by cuttings, which, if planted in july on a ſhady border, and duly watered, will take root in ſix or ſeven weeks, when they ſhould be taken up and planted into pots filled with light loamy earth, placing them in the ſhade till they have taken root; then they may be expoſed till october, at which time they muſt be removed into ſhelter.

Stemleſs, leaves linear-lanceolate three-nerved, peduncles radical one-flowered.

DESCRIPTIONS, &c.

1. Root perennial, ſmall, creeping. Stems ſeveral, weak and lax, three feet high, branched, hollow, round, leafy, with hairs ſcattered here and there on it, chiefly in the upper part. Leaves oppoſite, pale green, brittle and ſomewhat ſucculent, quite entire, a little hairy. The numerous ſtar-like flowers are viſible at a diſtance, and of a delicate ſtructure when cloſely examined. They are white and upright, in a terminating, dichotomous, many-flowered, divaricating, pubeſcent panicle, having a pair of ſmall leaves at each of the forkings. Calyx hairy at the baſe, the leaflets ſcarioſe-white at the edge. Petals ſpreading very much, cloven almoſt to the baſe, the ſegments linear-elliptic and divaricating. Styles conſtantly three. Fruiting calyxes turned downwards. Capſule elliptic, with a ſix-toothed mouth [u].

According to Dr. Withering, it is from five to twelve inches high; the ſtems very brittle; the whole plant hairy; the leaves rather ſtiff, underneath hairy only on the veins and midrib; the lateral fruitſtalks ſolitary, the terminating ones forming a kind of leafy panicle, widely ſtraddling, and rather turned down after flowering.

Linneus, in his Flora Lapponica (n. 186.) confounded this plant with Alſine media and Ceraſtium aquaticum. The former may be known in all its numerous varieties, from this and every other plant of its natural order, by the hairy line on one ſide of its ſtem, firſt pointed out by Mr. Curtis. The latter is diſtinguiſhed from this Stellaria by being viſcid, and much more hairy; its flowers much leſs conſpicuous; calyx more oval and leſs membranous; panicle more leafy; and eſpecially by all the ſtem-leaves being ſeſſile, neither are they lengthened out into ſo long a point; not to mention its five ſtyles, which are conſtant [x], as are the three ſtyles of this.

Native of Europe, in woods. In Britain, it is confined to moiſt woods and borders of clear ſhaded ſprings, in the northern counties of England, and the low-lands of Scotland; flowering in may. Found by Caſterton mill near Kirkby Lonſdale, &c. in Weſtmoreland, by Dr. Smith, near Kendal by Mr. Gough, near Darlington by Mr. Robſon [y]; formerly by Dr. Richardſon in Bingley pariſh [z]. In Scotland, about Broomholm and Langholm in Eſkdale, and at Springkeld and Hoddam-Caſtle, in Annandale abundantly: obſerved alſo by Dr. Parſons, at Meavis-Bank [a].

2. Root annual. Stem round, pubeſcent, very much branched, ſpreading every way, many times dichotomous, leafy, many-flowered. At each diviſion of the ſtem is a pair of leaves, which are acute and pubeſcent. The flowers come out ſingly from the diviſions of the ſtem, on round pubeſcent peduncles, an inch long, upright when in flower, but bent back as if broken when in fruit. Calyx pubeſcent, with acute leaflets, ſcarcely ſtriated, a nerve running along the middle, the margin white and ſcarioſe. Corolla white: petals length of the calyx, obovate, two-lobed at the end but not deeply divided; lobes obtuſe. Filaments nearly equal, a little ſhorter than the petals. Germ globular. Styles divaricating a little, length of the ſtamens. Stigmas obtuſe, recurved. Capſule ovate,

[y] Engl. bot. and With. [z] Ray ſyn. [a] Lightfoot.

ſmooth,

Digitized by Google

ſmooth, five-valved, opening at top. Seeds angular, rugged, collected into a ball.

Linneus had it from Gmelin, and it is a native of the mountains of Siberia. It has been confounded with a variety of the preceding. Haller deſcribes ſuch an one as the *dichotoma*, and then ſays that the two ſpecies do not differ. The true *dichotoma* is not known to be a native of Switzerland [b].

Introduced about 1774 at Kew. It flowers in july [c].

3. Native of Siberia, in bogs.

4. This plant at firſt ſight very much reſembles *Trientalis europæa*. The ſtem ſometimes has a branch or two. The leaves are veined above, but veinleſs beneath. Peduncles one-flowered, long, moſtly terminating, but ſometimes there is an axillary one or two.—Native of the mountains of Carinthia, in moiſt ſhady places [d].

5. Root perennial, creeping, weak, ſlender, jointed, ſending down fibres to a conſiderable diſtance. Stems ſeveral, growing thick together, about a foot high, decumbent at the baſe, ſlender and very delicate, then upright, ſupporting themſelves among buſhes or graſs, otherwiſe the leaſt breath of wind would lay them proſtrate; they are ſquare, jointed, rugged at the angles immediately under the joints, leafy, brittle, but with a ſtrong woody ſtructure in their inner part, as is the caſe with moſt of this tribe. Leaves in pairs at each joint, ſeſſile, long, acuminate, a little revolute and finely ſerrulate at the edge, or rather ſet with briſtles or fine prickles, the midrib ſharp and alſo ſet with ſmall prickles; above ſmooth, ſlightly glaucous, with a groove running along the middle. Flowers on very long, erect, rugged peduncles, from the axils of the upper pair of leaves, forming a ſort of dichotomous panicle. Calyx-leaves lanceolate, nerveleſs, a little membranous at the edges. Corolla white; petals obcordate, cloven about half way down. Filaments ſhorter than the corolla; five alternate ones furniſhed at bottom with a yellowiſh gland. Capſule globular, containing ſix or ſeven, kidney-ſhaped brown ſeeds [e].—According to Curtis, it is ſix-valved, and for the moſt part has five or ſix largiſh ſeeds, of a deep orange-colour and beautifully notched, like that of Chickweed (Alſine media) but larger. Gærtner deſcribes the capſule as globular, thin, ſubdiaphanous, ſix-valved, opening down to the baſe. Seeds about twelve, biggiſh, globular-reniform, beautifully muricated with pointed tubercles in diſtinct parallel rows, of a yellow-ruſeſcent colour. Receptacle ſhort, free, in the bottom of the capſule, compoſed of ſmall fungous tubercles, among which filiform umbilical chords go to the upper ſeeds.

Native of Europe. Very frequent in woods, among buſhes, and about dry hedge bottoms in England; flowering in may and june. Its large brilliant white ſtarry bloſſoms render it conſpicuous in the ſpring.

6. Root perennial creeping. The whole habit much like that of the preceding, but ſmaller and of a graſs-green not glaucous colour. Stem and flower-ſtalks perfectly ſmooth. Leaves entire, and ſcarcely even rugged at the edge. Panicle divaricated. Calyx-leaves pale, with three acute green ribs, which, as Dr. Stokes obſerves, are not to be found in *S. holoſtea*. Petals about as long as the calyx or longer, very deeply divided. Anthers of a pale reddiſh hue.

Native of Europe. The white ſtarry bloſſoms of this delicate plant prettily beſpangle furze-buſhes, heath, and low broom, on a gravelly or ſandy ſoil; and its herbage being concealed by the buſhes or graſs, and the ſtalks of the panicle very ſlender, the flowers ſeem ſuſpended in air. They are principally obſervable in june and july [f].

7. Very nearly allied to the preceding, but the leaves glaucous, and quite ſmooth about the edge. The ſtem alſo is ſmooth. Peduncles erect, axillary and terminating, alternate, ſometimes panicled. Flowers almoſt twice as large as in the preceding. Calyx acuminate, leſs acutely three-nerved. Petals obcordate, almoſt twice as long as the calyx. Anthers pale red [g].

[b] Smith ined. [c] Hort. kew. [d] Willdenow. [e] Smith brit. and engl. bot. Curt. lond. and With. [f] Engl. bot. [g] Smith brit.

Native of Germany and England. Flowering in june and july.—Mr. Stoneſtreet found it in the Iſle of Ely. Dr. William Sherard near Oxford, and Dr. James Sherard in Peckham fields. Ray found it abundantly on the fen banks of the Iſle of Ely [h]. Mr. Relhan, between Ely and Stuntney, on Bottiſham Load, Gamlingay bogs, and Bardolph fen near Wiſbeach. Dr. Sibthorp on Otmore, in Oxfordſhire. Dr. Abbot on Ampthill bogs, and in Ford-end ditches, Bedfordſhire. Dr. Withering, about Falmouth.

8. Leaves ſeſſile, quite entire, ſmooth. Peduncles from the forks, upright when in flower, reflexed when in fruit. Calyx-leaves ovate-lanceolate, much ſhorter than the petals. Annual.—Native of Germany, in moiſt meadows [i].

9. Root annual, ſmall and fibrous. Herb weak and ſlender, ſmooth, of a pale and ſomewhat glaucous green. Stems branched, quadrangular, leafy. Leaves rather elliptical, furniſhed with many parallel veins, entire but waved on the margin, tipped with a ſmall callous point. Flower-ſtalks axillary and terminating, ſpreading, generally three together, of which two are three-cleft and three-flowered, the remaining one ſingle-flowered, all furniſhed with membranous lanceolate bractes. Flowers ſmaller than in any other Britiſh ſpecies. Calyx-leaves three-nerved, the outermoſt fringed. Petals greeniſh-white, ſhorter than the calyx. Dr. Stokes has obſerved that the ſtyles vary from three, the natural number, to four or five. The peculiar inflorescence, the ſhort petals, the form and ſtructure of the leaves, mark this ſpecies with ſufficient preciſion [k].

Mr. Curtis remarks, that the leaves are united at the bottom, above half an inch in length, and two or three lines in breadth, frequently growing to one ſide of the ſtalk, and bending towards each other ſo as almoſt to touch at the points, and that the tips are conſpicuouſly brown and callous: alſo, that the flowers would be terminating, did not a new ſhoot, rather than a continuation of the ſtem, proceed from the panicle. Seeds numerous, minute, roundiſh, flattened, wrinkled, of a reddiſh brown colour.

Native of Europe, on the ſides of ſprings, rivulets, ditches and wet ſpringy meadows. In England not uncommon. It flowers in june and july.

10. Stem decumbent, herbaceous, tender. Branches angular, erect, a little ſubdivided, weak, ſmooth, a hand in length. Leaves oppoſite, ſeſſile, acute, ſmooth, length of the internodes. Flowers axillary and terminating, two or three together, on capillary one-flowered peduncles, longer than the leaves. Calyx ſmooth.—Native of Japan, by way ſides; flowering there in april [l].

11. Root perennial, creeping. Stems diffuſe, branched at the bottom, leafy, marked with a ſlender alternate hairy line, as in the common Chickweed. The flower-ſtalks, which grow about two together at the extremity of the ſtem, are downy in every part. Leaves oppoſite, lanceolate or ſomewhat ſpatulate, blunt, entire, ſmooth, often leaning to one ſide. Flowers erect, white. Calyx-leaves obtuſe, ſingle-ribbed, downy and viſcid at the baſe, membranous in the margin. Petals about twice as long as the calyx, cloven half way down, narrow. Styles ſometimes four or five; teeth of the capſule double their number. Seeds rough, pale brown. Linneus, after publiſhing an excellent deſcription in his Flora Suecica, confounded other plants with it.

Native of the mountains of Lapland, Norway, Switzerland, France, Piedmont and Scotland. Mr. Dickſon firſt made it known as a Britiſh native. He found it on Ben Nevis in 1789. Mr. Mackay alſo gathered it there and on the mountains to the north of Invercauld. It flowers in june [m].

12. This is very different from the preceding. Root creeping, filiform. Branches or ſtems quite ſimple erect numerous from the root. Leaves ſmooth. Peduncles terminating, one, two or three together, erect. It differs from the next above chiefly in the ſmoothneſs of the leaves, and its peduncles being terminating,

[h] Ray ſyn. [i] Ehrhart and Willdenow. [k] Engl. bot. [l] Thunberg. [m] Engl. bot.

Digitized by Google

whereas that produces two peduncles which are upright below the top of a procumbent ſtem: the habit alſo is very different.—Native of the mountains of Carinthia.

13. This is an annual plant, with the petals a little larger than the calyx.—Native of Sweden and Norway [s].

14. This is a ſmall plant, with the appearance of a *Sagina*. Leaves radical, awl-ſhaped, collected into a tuft. Stem a finger's length, filiform, for the moſt part naked; cloven at top into two peduncles, with a pair of leaves under each, and another peduncle in the middle, with two leaflets [o]. The petals are only ſlightly emarginate, and therefore very near thoſe of *Arenaria*; of the ſame ſize with the calyx.—Native of the mountains of Lapland. Perennial [p].

15. This alſo is a ſmall plant, with the leaves ſomewhat fleſhy, and ſome of thoſe on the ſtem ciliate at the edge with long hairs. Flowers large in proportion to the plant. Calyxes naked: leaflets ovate, obtuſe. Petals by no means bifid; ſcarcely emarginate.—Native of Groenland [q].

16. Root annual, fibrous. Stem round, a ſpan high, pubeſcent and ſomewhat clammy with ſpreading hairs. Branches alternate, almoſt the length of the ſtem. Leaves ſeſſile, ovate at the top, linear and narrower towards the baſe, hairy beneath and along the edge, but ſcarce apparently ſo above. The firſt flower comes from the forking of the ſtem; the reſt alternately from the axils of the branches: all of them biggiſh. Peduncles ſtraight, longer than the leaves. Calyx clammy, like the whole plant, purpliſh at the tip, as are alſo the floral leaves. Corolla bell-ſhaped, longer than the calyx, white, very blunt, with the petals ſcarce manifeſtly emarginate. Stamens white, the ſame length with the calyx. Anthers blueiſh. Germ globular. Styles three, the length of the ſtamens.—Native of Spain [r].

17. Leaves cluſtered at the root, half an inch long, acuminate, very ſlightly three-nerved, rugged at the edge. Peduncles radical, upright, an inch and half long, filiform, one-flowered. Calyx-leaves lanceolate, ſomewhat membranous at the edge, acute, three-nerved. Petals linear, cloven to the very baſe, of the ſame length with the calyx. Stamens ſhorter than the petals. Germ globular. Styles three, filiform. Flower of the ſame ſize as in *St. graminea*. Perennial. Native country unknown [s].

DESCRIPTIONS, &c.

1. This is an annual plant, reſembling *Theſium alpinum*. Root ſlender, fuſiform, ſcarcely branched, yellow on the outſide, white within. Stem upright, from a hand or half a foot to a foot in height, very much branched from the very bottom. Leaves alternate, ſeſſile, acute, quite entire, ſmooth, ſpreading and bending down, ſhaped like a ſparrow's tongue, whence its old name, which Linneus has adopted as a trivial. The ſtem and branches are terminated by long looſe interrupted leafy ſpikes. The flowers are ſeſſile, three, four or five together, in the axils of two or rather three leaves, of which the two ſide ones are ſhorter, and may be conſidered as bractes. Corollas ſmall, greeniſh with yellow tips; permanent, diſtended into a ball by the growing ſeed, and involved in wool at the baſe [t]. Seed a ſmall ſuperior nut, ovate-beaked, with a membranous coat, and wrapped up in the corolla. Rind or epidermis very thin, pale, eaſily ſeparating. Shell thin, brittle, dark, ſmooth, ſhining, ending in a beak which is ſlightly curved inwards, and marked on one ſide with a raiſed line; one-celled, valveleſs. Seed adapted to the cavity of the ſhell, whitiſh [u].

Native of Germany, Switzerland, France and Italy. It flowers in july and auguſt.

This plant is acrid, bitter and purgative. Gmelin ſays, that the Ruſſians require half a drachm or two ſcruples for a purge; whereas twelve grains are ſufficient for other people. This difference he thinks to be occaſioned by the free uſe of ſpirits among the Ruſſians, which deſtroys the tone of the ſtomach [x].

2. Perennial. Native of Siberia [y].

DESCRIPTIONS, *&c.*

1. Root long, round, with lateral horizontal fibres. Stem from one to three feet high, erect, four-cornered, hirſute, ſometimes in hedges near the ſea-coaſt in a manner ſcandent. Branches numerous, ſhorter, ſcattered, alternate, oppoſite, three or four together, quadrangular, leafy, hirſute. Leaves ſmall, ſeſſile, ovate-lanceolate, obtuſe, ſerrate, thickiſh, hirſute: with ſmaller leaves in the axils of the larger. Flowers few, axillary, among the terminating leaves, ſmall, white or blue. Border of the corolla almoſt equal, four-cleft: upper ſegment a little wider, almoſt upright, ſpreading, emarginate; the two ſide ones and the lower ſegment equal, roundiſh, entire, convex. Capſule oblong, acuminate. Seeds roundiſh, minute [a].

Jacquin ſays it is perhaps a biennial plant, two or three feet high: the ſtems hirſute, moſtly hexagonal, but ſometimes pentagonal. Leaves acute, viſcid. Stipules ovate, entire, length of the calyx, two under each flower. Corolla blue and ſoon falling.

Native of Jamaica, and very common by the ſea-ſide, in all the ſouthern parts of the iſland: it has a pleaſant aromatic ſmell, with a bitteriſh taſte, and will probably prove an excellent ſtomachic and aperitive [a].

2. Stem herbaceous, a foot high, erect, branched, leafy, quadrangular at bottom, but the angles are rounded towards the top, hirſute, viſcid. Branches ſimple. Leaves ſeſſile, ternate, wider at the baſe and connate, toothlet-ſerrate, ſpreading, nerved, pubeſcent. Flowers on very ſhort peduncles, axillary, in threes, ſolitary. Corollas blue, ſmall. Calyx almoſt five-leaved: ſegments awl-ſhaped, permanent, ſhorter than the corolla, hirſute. There are two leaflets, very like the ſegments of the calyx, at the baſe among the others; ſo that the calyx is as it were ſeven-leaved. Corolla almoſt equal, a little bellying at the baſe, more contracted in the middle: border four-cleft; upper lip erect wider, obtuſely bifid, ſhorter; the three lower ſpreading, flat, blunt at the top; throat ſquare, marked with lines, on the outſide below the ſegments yellow, compreſſed. Stigma a little curved in, widened, funnel-form, equal. Capſule oblong-conical, five-cornered, compreſſed at the top, two-celled, with a large, ovate, acute, contrary partition, four-valved.—Native of Jamaica [b].

3. This is a ſmall annual herbaceous plant, with a pleaſant aromatic ſmell. Stem generally bent to one ſide, with many ſpreading branches from its baſe, four-ſided, hairy, viſcous, from ſix to twenty-four inches high. Leaves linear, below oblong, above cordate, ſerrate, hairy, viſcous. Flowers axillary, ſmall, violet-coloured. Two lanceolate bractes preſs on the calyx. Tube of the corolla compreſſed, longitudinally wrinkled, twice the length of the calyx: upper lip broad, emarginate; under lip three-parted. Stamens within the tube.

Native of Coromandel: found on dry paddy fields, after the crop has been cut. The Telingas call it Boda-ſarum [c].

4. Native of the Eaſt Indies. Found by Koenig.

DESCRIPTIONS, *&c.*

1. This, from the figure given by Cavanilles, ſeems to be a tree of moderate ſize, with ſmooth, veined, lanceolate leaves; the fruit appears to conſiſt of five rather large ovate capſules diſpoſed in a ſtellated direction on the footſtalk; they are of a red colour and contain three or four large black round ſeeds in each. Native of China.

Cavanilles appears to doubt whether it be truly diſtinct from the following ſpecies or not: the figure he gives is from a Chineſe drawing, in which it is uncertain whether the painter intended it for a diminiſhed repreſentation or of the natural ſize.

2. This is a tall tree, with a ſtem of two feet in diameter, thick branches, covered with a thick aſh-coloured bark, and furniſhed with alternate, ſmooth, veined, lanceolate leaves: the leaves however are only produced at the upper part of the ſhoots; and are in general about nine inches long and three broad: the flowers are produced in ſparſe faſcicles at the tips of the ſhoots: the capſules are rather large, ſmooth, ovate, and ſtand by fives in a ſtellated direction; each capſule containing ſix, ſeven, or eight moderately large round ſeeds.—Native of Malabar, Amboina, &c.

According to Rumphius the ſeeds are conſidered as eſculent by the inhabitants of Amboina, who roaſt them for this purpoſe, while the capſules are burned for the preparation of the pigment called *Caſſomba*.

3. A tree of ſixty feet high, branching in a ſpreading manner at the top: leaves alternately ſcattered, and on long footſtalks: they are ſmooth above, downy beneath, where they are alſo of a reddiſh caſt; the flowers are borne on panicles, the footſtalks of which have each a ſtipule at the baſe: the capſules are reniform, with pointed tips, and are diſpoſed in a circular direction: their interior ſurface is covered with a pungent villus: the down of the germ gradually lengthens as the fruit advances, and at length runs into innumerable long briſtly hairs ſurrounding the footſtalks of the capſules. Some of the capſules are apt to fail. The general number of ſeeds is five in each. Native of Guiana, in the woods of Sinemare, and near the river Galibien.

4. Stem arboreſcent: leaves alternate, approximate, and towards the tip obſcurely trilobate: capſules oblong, ſubreniform, with pointed tips; they are downy on the outſide, and covered within by a white membrane beſet with innumerable ſhort ruſeſcent hairs: ſeeds ſeveral, hanging from the internal edges of the capſules, and covered with briſtly hairs.—Native of Senegal [o].

5. Trunk erect, growing to a very great ſize. Bark aſh-coloured, and a little ſcabrous. Branches numerous, ſpreading irregularly; bark as on the trunk, but ſmoother. Leaves alternate, about the extremities of the branchlets, petioled, conſiderably broader than long, five-nerved, ſoft and a little downy; generally, when full grown, from nine to twelve inches broad, and from ſix to nine inches long. Petiole round, a little downy, about nine inches long. Stipules two, erect, lanceolate, inſerted into the petiole near its baſe. Panicles terminating, ſmall, numerous, red like coral, covered with many red ſtellated hairs. Flowers numerous, about an inch long. Calyx inferior, funnel-form, five-toothed at the mouth, covered on the outſide with red ſtellated hairs, withering. Filaments ſcarcely any. Anthers about thirty, kidney-form, ſeſſile round the border of the extremity of the receptacle. Receptacle of the piſtil cylindric, bent a little, length of the calyx, round, ſmooth, bearing five oval germs on its top. Styles ſhort, recurved. Stigmas acute. Capſules from one to five coming to maturity, leguminous, pedicelled, pendulous, leathery, one-celled, one-valved, opening on the outſide long before the ſeeds are ripe. Seeds two, one adhering to each margin of the gaping capſule alternate, about the ſize and ſhape of a Kidney bean.

This tree caſts its leaves during the cold ſeaſon. It flowers in april, and then appears as if entirely covered with fine ramifications of red coral. Soon after the leaves make their appearance.

Native of the mountainous parts of the Rajahmundry Circar. Called by the Telingas Caraka.

6. Trunk erect, very ſtraight, with the top large and ſhady. Bark aſh-coloured, very ſmooth; its outer coat thin, tranſparent, covered with a farinaceous ſubſtance, and peeling off like the pellicle of the birch-bark; inwardly it is fibrous and netted. Leaves about the extremities of the branches, alternate, petioled, five-nerved; very downy, from nine to twelve inches each way. Petiole nearly as long as the leaf, round, downy. Panicles terminating, pretty large; every part covered with a glutinous, farinaceous, yellow down. Bractes lanceolate. Flowers ſmall, numerous, yellow, male and hermaphrodite mixed, but with a ſmall proportion of the latter. The hermaphrodite flowers have an inferior calyx, bell-ſhaped, five-toothed, the diviſions acute; on the inſide of each diviſion near the baſe is an inverſe-hearted hairy gland. Filaments ten, ſhort, alternately longer, united below into a thin ſheath, which girds the baſe of the germs. Anthers large, two-lobed, alternately larger. Germs five, placed on a thick ſhort pedicel. Style ſhort, thick. Stigma five-lobed. Capſules five, leguminous, united in form of a ſtar, one-celled, one-valved, opening lengthwiſe, on the outſide covered with yellow down, and many ſtiff ſtinging hairs. Seeds from three to five, oblong, cheſtnut-coloured, inſerted alternately into the margins of the capſules. The calyx, ſtamens, and columnar receptacle, are the ſame in the male flowers: but the piſtil has the rudiments of germs only, without any appearance of a ſtyle.

This is a very large tree, chiefly a native of the mountainous countries of the coaſt of Coromandel; it caſts the leaves about the end of the wet ſeaſon, and flowers during the cold ſeaſon; the leaves come out with the fruit about the beginning of the hot ſeaſon. The wood is ſoft and ſpongy; towards the centre of large trees it is reddiſh. It ſeems to be applied to

[o] Cavanilles.

little

Digitized by Google

little uſe, except to make Hindoo guitars. The water in which green branches were kept for examination became thick like a clear glutinous jelly. The bark is exceedingly aſtringent, and tinges the ſaliva reddiſh. The ſeeds are roaſted to be eaten by the natives, and taſte very like parched Peas. The Telingas call the tree Cavallie[f].

7. This is a very lofty tree. Leaves large, alternate, cluſtered at the end of the branches, on long petioles, cordate, quite entire, three-lobed or five-lobed, with the ſinuſes rounded and bluntiſh; quite ſmooth, five-nerved. Panicle large, woody, ſomewhat mealy. Flowers hermaphrodite, the ſame ſize as in the *fœtida*. Segments of the calyx hoary without, ſmooth within, yellowiſh. Column of ſtamens ſhorter than the calyx, terminated by numerous ovate anthers, which cover the baſe, although they are placed upon the column. Germ angular, hoary. Style filiform, hoary. Stigma emarginate[g]. The pericarp is ſingular. When ripe it parts longitudinally into five cells, which become ſo many horizontal capſules, like the follicles of the *Aſclepias*, and open longitudinally by the upper future; the ſeeds are faſtened to the ſides of the future in a ſingle row.

Native of Japan and China. Linneus had the leaves in his herbarium, under the name of *Hibiſcus ſimplex*. He referred them to that genus, never having ſeen the flowers. Chevalier Murray communicated it to the younger Linneus, from the Padua garden, where it flowered every year in the open air.—It was cultivated in 1757, by Hugh Duke of Northumberland[h].

Hibiſcus ſimplex of *Lin. ſpec.* and of our Dictionary, n. 13. muſt therefore be expunged, being the ſame with this.

8. This is a tree above the middle ſize, with ſpreading unarmed branches. Leaves on a very long petiole: leaflets lanceolate, quite entire, ſeven or nine, ſmooth, glaucous, placed in a ring, and ſeſſile. Flowers monoecous, fetid, in ſubterminating racemes. Calyx five-parted, ſmooth, large, ſpreading, of a cinereous-glaucous colour. Stamens about fifteen, connected. Style one. Germ peduncled. Capſule roundiſh-ventricoſe, ſubcompreſſed, corticoſe, ſmooth, five-celled, two-valved. Seeds numerous, oblong-ovate, each on its proper pedicel hanging from each valve, as in a legume.

Native of the Eaſt Indies, Cochinchina, &c. The wood is pale, laſting and does not ſplit; it is therefore very proper for the turner, and being well varniſhed makes handſome vaſes, &c. It has nothing of the ill ſmell which the flowers have. The leaves and eſpecially the bark are aperient, repellent, diuretic and diaphoretic. The ſeeds are oily, and are not eaten in Cochinchina; on the contrary if they are ſwallowed incautiouſly, they bring on nauſea and vertigo[i]. This happens probably when eaten raw.

It was cultivated in 1690, in the royal garden at Hampton-court[k].

Theſe plants were originally placed in the claſs Monoecia; from thence they were removed into the claſs Monadelphia, and finally they are placed in that of Dodecandria.

PROPAGATION AND CULTURE.

Propagated by ſeed; and treated in the ſame way as Sida.

DESCRIPTIONS, &c.

1. This is a tree, with the leaves alternate, petioled, ſimple, ovate-oblong, quite entire, ſmooth. Spikes alternate, naked, very long. Flowers ſmall, ſcattered, ſeſſile[l].—Native of the Eaſt Indies. Dr. Smith refers it to the genus Antideſma[m]: which ſee. It was introduced here about 1757, by Hugh Duke of Northumberland; and flowers in auguſt[n].

2. Leaves alternate, on ſhort petioles, nearly bifarious or two-faced, oval, entire, ſmooth, from two to four inches long, and from one to two broad. Stipules lanceolate. Spikes filiform. terminating, many-flowered. Bractes minute, one-flowered. Flowers very ſmall, approximated.—In the Male tree; perianth inferior, cup-form, obtuſely four-toothed. Corolla none. Filaments two, four times longer than the calyx. Anthers thin, ſingly oval.—In the Female; calyx inferior, cloſely embracing three fourths of the germ, four or five-toothed. Corolla none. Nectary, a yellow fleſhy ring, ſurrounding the baſe of the germ. Germ obliquely ovate. Styles two, ſpreading; one of them always two-cleft. Stigmas ſimple. Drupe minute, ſucculent, one-celled. Nut one-celled, very ſmall.

It is a large tree, native of mountainous parts of the Circars, and flowers in june.

The fruit, when ripe, is eaten by the natives. The wood ſerves for various uſes[o].

DESCRIPTIONS, *&c.*

Juſſieu deſcribes theſe as ſhrubs reſembling a Phylica or a very ſmall Fir. Leaves linear, cluſtered, in whorls or ſpirally imbricate; flowers in cloſe ſpikes, either along a tomentoſe terminating axis, or in the forkings of the branches. Allied to *Protea*, but having a corolla; to *Phylica*, but one-petalled and one-ſeeded; perhaps more nearly allied to *Globularia* or *Selago*[p]: with which laſt Linneus formerly united it.

1. Branches alternate, ſtiff, rugged with the remaining baſes of the leaves. Leaves whorled in cluſters, acute, ſmooth. Spikes oblong, terminating, ſeſſile, imbricate; with bractes the length of the flowers. Glumes two-valved, ſeſſile, compreſſed, acute, one-flowered. Perianth cartilaginous, very ſhort, with a five-toothed mouth, deciduous with the ſeed, ſo ſmooth that it can ſcarcely be held. Corollas woolly on both ſides; tube filiform; border with five, almoſt equal, linear, hirſute ſegments. Filaments filiform, almoſt equal, length of the corolla, with incumbent anthers.—Native of the Cape of Good Hope, by rivulets[q].

2. Stature of an *Erica* or Heath. Leaves lanceolate, acute, even, more convex beneath, as it were two-keeled, with the keels remote and blunt. Spike terminating, ſeſſile, growing out. Corollas even.—Native of the Cape of Good Hope[r].

3. This is very like the firſt ſpecies, but the branchlets with the head hang down.—Native of the Cape of Good Hope, where it was found by Thunberg[s].

STILLINGIA. (*So named by Alexander Garden*, (ſee Walter carol. 239.) *in honour of Benjamin Stillingfleet, Eſq. author of* The Calendar of Flora, *and* Obſervations on Graſſes, *publiſhed, with ſeveral Treatiſes tranſlated from the* Amoenitates Academicæ, *under the title of* Miſcellaneous Tracts relating to Natural Hiſtory, &c. ed. 1. 1759.—2, 1762.—3, 1775. Lond. 8°.)
Lin. gen. Reich. n. 1187. *Schreb. n.* 1470. *Juſſ.* 390.
Claſſ. 21. 8. Monoecia Monadelphia.
Nat. order of *Tricoccæ*. *Euphorbiæ*, Juſſ.

GENERIC CHARACTER.

* *Male* flowers digeſted in an amentaceous ſpike.
CAL. *Perianth* many-flowered (ſeven-flowered), coriaceous, hemiſpherical, pitcher-ſhaped, quite entire; with two goblet-ſhaped glands.
COR. one-petalled, fiſtular-funnelform, widening gradually, much narrower than the calyx: *mouth* undivided, torn, ciliate.
STAM. *Filaments* two, filiform, twice as long as the corolla, divaricating at the top, very ſlightly united at the baſe. *Anthers* twin-reniform.
* *Female* flowers few, at the baſe of the ſame ſpike.
CAL. *Perianth* one-flowered: the reſt as in the Males.
COR. ſuperior.
PIST. *Germ* roundiſh, between the calyx and corolla. *Style* filiform. *Stigmas* three, diſtinct, recurved.
PER. *Capſule* tricoccous, ſubturbinate, ſubtrigonal, three-celled, ſurrounded at the baſe by the widened calyx.
SEEDS ſolitary, oblong, ſubtrigonal, with a tranſverſe ſcar on the inner ſide.

ESSENTIAL CHARACTER.

MALE. *Cal.* hemiſpherical, many-flowered. *Cor.* tubular, eroſe.
FEM. *Cal.* one-flowered, inferior. *Cor.* ſuperior. *Style* trifid. *Capſ.* tricoccous.

SPECIES.

1. Stillingia ſylvatica.
Lin. ſyſt. 866. *Reich.* 4. 197. *mant.* 126.

DESCRIPTION, *&c.*

This is a ſhrub, with many upright, round, milky ſtems, three feet high, terminated by a ſpike. Two branches commonly ſpring out at the baſe of the ſpike. Leaves alternate, petioled, remote, elliptic, ſerrulate, ſhining, ſpreading. Spike or ament terminating, ſeſſile. Flowers ſmall, yellow. It is accounted a ſpecific in Siphilis[t].

Native of Carolina in pine woods. Found there by Dr. Garden. Introduced in 1787, by Thomas Walter, Eſq.[u]

STIPA.
Lin. gen. n. 90. *Reich. n.* 96. *Schreb. n.* 121. *Juſſ.* 30.
Claſſ. 3. 2. Triandria Digynia.
Nat. order of *Gramina*, *Gramineæ* or *Graſſes*.

GENERIC CHARACTER.

CAL. *Glume* one-flowered, two-valved, lax, acuminate.
COR. two-valved: *outer valve* terminated at the tip by a very long twiſted awn, jointed at the baſe and ſtraight: *inner valve* length of the outer, awnleſs, linear.
Nectary two-leaved: *leaflets* linear-lanceolate, membranaceous, gibbous at the baſe.
STAM. *Filaments* three, capillary. *Anthers* linear.
PIST. *Germ* oblong. *Styles* two, hirſute, united at the baſe. *Stigmas* pubeſcent.
PER. none. *Glume* adnate.
SEED one, oblong, covered.

ESSENTIAL CHARACTER.

Cal. two-valved, one-flowered. *Cor.* outer valve with a terminating awn, jointed at the baſe.

Desfont. atlant. 98. *t.* 29.
Leaves radical ſtiffiſh filiform, panicle diffuſed, awns naked capillaceous.

14. Stipa tortilis. *Twiſted-awned Feather-graſs.*
Desfont. atlant 99. *t.* 31. *f.* 1.
Panicle ſpiked rolled in at the baſe, inner calyx villoſe, awns twiſted villoſe at bottom.

DESCRIPTIONS, *&c.*

1. Root perennial, fibrous, tufted. Culms ſimple, a foot high, upright, ſlender, round, very ſmooth, without knots, clothed entirely with the ſheaths of the leaves. Leaves rolled in and briſtle-ſhaped, mucronate, glaucous, ſomewhat rugged on the edges: ſheaths very long and much widened, embracing, ſtriated, ſmooth, ſhining within. Stipule lanceolate, growing to the leaf. Panicle ſimple, few-flowered, lying within the ſheath of the upper leaf. Flowers very large, from four to ſix. Calyx-glumes nearly equal, lanceolate, ſcarioſe, concave, nerved, ſmooth, narrowed into a membranaceous very tender awn, longer than the valves. Floret awl-ſhaped, round, nerveleſs, ſhorter than the calyx, ſilky-briſtly at the baſe. Awn from a joint at the tip of the outer glume, the longeſt of any, being from ſix to twelve inches in length, or even more, nodding and curved in, acute, angular, twiſted at the baſe, clothed almoſt the whole length with very fine white ſoft pellucid ſilky diverging hairs, and at length falling together with the permanent hardened corolla, inveſting the ripe ſeed, and ſcattered round the fields and rocks, to produce a new progeny [x].

The feathered awns are a beautiful and remarkable feature, at once diſtinguiſhing this from all our other graſſes [y].

Cluſius firſt obſerved this elegant graſs near Baden, and in ſeveral parts of Auſtria and Hungary. It has ſince been found in ſeveral places in Germany, France, Italy, Spain, Barbary and Siberia. In Dillenius's edition of Ray's ſynopſis it is ſaid, that Dr. Richardſon found it, in company with Thomas Lawſon, on the lime-ſtone rocks hanging over a little valley, called Long Sleadale, about ſix miles north of Kendal in Weſtmoreland.——Hudſon gives no other place of growth; but in the ſecond edition of Dr. Withering's botanical arrangements, Mr. Alderſon is mentioned as having found it near Kendal: but Mr. Gough, who lives there, has never found it, nor has he heard of any perſon who found it, except thoſe above mentioned: there is therefore reaſon to fear that it has been exterminated [z].

Johnſon, the editor of Gerarde's herbal, ſays it was nouriſhed for the beauty in ſundry of our Engliſh gardens; and that it was worn by ſundry ladies and gentlewomen inſtead of a feather, which it exquiſitely reſembles.

2. Root perennial, (or biennial.) Leaves convoluted, even, rigid, round, almoſt filiform. A torn acute white little membrane (ſtipule) crowns the ſheath. Culm erect, ſlender, jointed at bottom. Panicle lax, elongated. Peduncles capillary, long, angular, rough, few-flowered: flowers pedicelled. Calyx-glumes membranaceous, lax, awl-ſhaped, twice as long as the corolla; which is round, coriaceous, truncate, ſlender, with the glumes cloſe rolled in, villoſe at the baſe. Awn terminating, twiſted at bottom, pubeſcent. Seed ſlender, elongated [a].

Native of France, Switzerland, Sileſia, Carniolia, Barbary. Haller and Scheuchzer unite it with the next ſpecies. It was introduced in 1772, by Monſ. Richard; and flowers in july [b].

3. This reſembles the preceding ſpecies very much, but the leaves are not round with a longitudinal groove; but ſtiffer, ſhorter, leſs rugged, more unfolded and ſomewhat pubeſcent on the upper ſide. Calyx not whitiſh but bay-coloured. Awns ſhorter, and when more advanced variouſly curved [c].

Culms many, about two feet high, hard and ſolid, ſurrounded with ſtiff ſtraight leaves like a ruſh at their baſe; they are villoſe on the upper ſurface, principally at their baſe. Stem-leaves one or two, forming a ſheath round the ſtem, contrary to the ſun's apparent motion, and rendering it thick at that place. The panicle remains compreſſed near the ſheath, from which iſſue brown membranous flowers, compoſed of a two-valved calyx, terminated by two awns half an inch long or more; and a two-valved corolla, as ſhort again as the calyx, the outer valve lengthened into an awn which is ſtraight at firſt, but afterwards bends back as if it were broken in the middle: this awn is ſimple and not feathered.—The ſynonym from Ray and Vaillant, in Reichard's and Willdenow's editions of Species Plantarum, belongs to *Avena pratenſis* [d].

Native of France, Germany, Switzerland and Italy. Perennial.

4. Root perennial. Culms two feet high. Leaves narrow. Panicle ſubſpiked, with two or three-flowered peduncles. Calyx length of the ſeed. Seed round, pubeſcent with few villoſe hairs. Awn length of the the calyx.—Native of the country about Montpelier [e].

5. This has the appearance of the *juncea*. Culms many, a foot and half high, quite ſimple, erect, ſheathed with leaves. Root-leaves abundant, awl-ſhaped, rigid, two inches long: on the culm three, longer, the uppermoſt ſheathing, higher than the culm. Sheaths ſtriated, bearded at the mouth, ciliate at the edge. Panicle a ſpan long. Spikelets many at each tooth of the common peduncle. Calyx very much attenuated, three times as long as the ſeed, ſmooth. Outer valve of the corolla hairy, ciliate. Awn a hand length, beyond the middle twiſted very much and hairy.

Forſkahl's plant differs only in having the ſheaths and radical leaves pubeſcent even on the outſide.—Stipa tenaciſſima differs in having the panicle contracted, with the awns three times ſhorter, leſs twiſted; the leaves more rigid, longer, quite ſmooth on both ſides; the ſheaths very finely ſtriated, the uppermoſt not ſpathaceous, the mouth of the ſheaths woolly [f].

Found by Vahl every where about Tunis, and by Forſkahl in Egypt.

6. Habit of *Avena*. Culm erect, jointed. Leaves hard, ſmooth, convoluted. Flowers panicled, approximating, numerous. Panicle erect, contracted, yellowiſh.

[x] Smith brit. [y] Withering. [a] Idem. [b] Desfontaines. [c] Hort. kew. [d] Linn. ſpec. [e] Villars. [f] Linn. [f] Vahl.

Digitized by Google

lowiſh. Calyx-glumes concave, elongated, acute, almoſt equal, membranaceous at the edge and tip. Corolla ſhorter, elongated, round, coriaceous, with white villoſe hairs; the outer glume cloſely involving the other. Awn jointed, below twiſted and villoſe, above · iked. Seed ſlender, elongated. It grows in a cloſe tuft. The inhabitants make ropes, baſkets and mats of it [g].—Native of Spain and Barbary, on ſandy hills.

7. Native of the Cape of Good Hope.

8. Root perennial, creeping, producing many culms. Leaves even, on the upper part of the culm ſhort. Culm even, a foot and half high. Spike narrow, ſcarcely the length of a finger. Flowers ſeſſile, ſcarcely pubeſcent, villoſe at the baſe. Awn terminating, ſcarcely a finger's length, twiſted, ſomewhat hairy, beyond where it is twiſted even.—Native of the Cape of Good Hope [h].

9. Culm a foot and half high, erect, ſtriated, ſheathed, ſmooth: ligule or ſtipule membranaceous. Panicle branched, ſpreading. Pedicels capillary, ſeveral to each tooth. Calyx-valves a little longer than the ſeed, ending in a point, ſharp at both ends, duſky purple at the baſe, from the middle to the tip membranaceous. Outer valve of the corollas obovate, bearded at the baſe, with fulvous hairs, muricate at the tip. Awn two inches long, variouſly bent, bearded at the baſe, below ſlightly pubeſcent, ſomewhat rugged backwards, pale yellow. Inner valve rigid, awl-ſhaped, incloſed by the outer.—Native of Braſil, on monte Video. Found by Thouin [i].

10. Culms ſlender. Upper leaf ventricoſe, length of the panicle, which is compoſed of conjugate one-flowered peduncles. Calyx-glume one-flowered, pale, two-valved, equal. Awn of the corolla terminating, twiſted, jointed at the baſe, naked, length of the peduncles. This graſs is ſmaller than Avena ſativa.—Native of Virginia [k].

11. This graſs is ſcarcely a foot high, with the appearance of an Avena. Culm even, the thickneſs of a ſmall thread. Panicle ſimple ſcarcely ſubdivided, lax, weak. Pedicels membranaceous, ancipital, bluntiſh. Awn of the calyx and corolla of the ſame length.—In the mantiſſa it is ſaid to be a raceme, with the peduncles one-flowered, depreſſed, margined ſo as to be in a manner membranaceous. One valve of the calyx the length of the ſeed, the other very ſhort, both acuminate. Awn of the ſeed terminating, flexuoſe, a little longer than the ſeed. The laſt flower but one ſeſſile. Native of Spain, where it was obſerved by Loefling [l].

12. This differs from the firſt ſpecies in having rigid, glaucous, flattiſh leaves, ſtriated on one ſide, wider, ſerrate, with a very long awn hirſute on every ſide from the baſe to the tip.—Native of Barbary about Maſcar and Tlemſen.

13. Roots perennial, fibrous, flexuoſe, long. Culms many from the ſame head, ſlender, erect. Leaves ſmooth, convoluted, ſhort. Panicle elongated, bowed. Peduncles long, many from the ſame knot, capillary, unequal, many-flowered: flowers pedicelled, thin, elongated. Calyx one-flowered: glumes unequal, membranaceous, channelled, narrow, acute. Corolla ſhorter, ſlender, ſmooth, round: glumes coriaceous, cloſely involuted. Awn capillary, naked, twiſted at the baſe. Seed thin, elongated, ſmooth.

Native of dry hills near Maſcar, and in the kingdom of Tunis.

14. Culms erect, many from the ſame head. Leaves ſmooth, convoluted; the radical ones almoſt capillary. Panicle yellowiſh, wrapped at the baſe in a ſheathing leaf. Branchlets preſſed cloſe. Flowers deciduous. Calyx-glumes awl-ſhaped, membranaceous, white, ſhining, acute, almoſt equal, lax. Corolla deciduous, round, villoſe on the outſide; with the glumes cloſely convoluted. Awn villoſe at the baſe, twiſted, ſmooth above, when the ſeed is ripe, knee-jointed and terminating. Seed elongated, thin, with a longitudinal groove on one ſide.

The flowers are deciduous and very numerous, ſtick to the clothes of paſſengers, and incommode them by tickling and pricking them.—It is an annual graſs, native of Barbary in fields [m].

DESCRIP-

Digitized by Google

DESCRIPTIONS, &c.

1. This, like all the reſt, is a ſhrubby plant. Leaves awl-ſhaped, rolled in, bowed backwards, rigid, pungent, like thoſe of Juniper, even except at the baſe [n]. In ſtrictneſs, according to Gærtner, the partial calyx is not ſuch, but the chaffs neareſt to the florets are inſtead of one.

The ſtem riſes two or three feet high, ſending out ſlender branches from the ſides. Leaves ſhort, linear, for the moſt part hooked, of a grayiſh colour, and placed irregularly round the branches. The flowers are produced in ſingle heads at the end of the branches, and are of a pale yellow colour. The florets are ſingle, and peep out between the ſcales of the calyx. It flowers in auguſt, but ſeldom produces good ſeeds in England.

[2. This is a diſtorted little ſhrub, like Heath. Leaves cluſtered, linear, ſharp. Flowers terminating, ſeſſile. Common calyx ſubſquarroſe:—partial imbricate (ten), cylindric, two-flowered; one floret tubular, hermaphrodite, the other ligular, neuter. Corolla hemiſpherical. Germ inferior: two ſtigmas. Down ſeſſile, feathered. Receptacle tomentoſe.

3. Stems filiform, ſomewhat woody, decumbent, determinately branched, aſh-coloured at the end, the ſize of wild Thyme. Leaves alternate, ſeſſile, elliptic, very ſharp, the ſize of Herniaria, white-tomentoſe above, naked beneath, recurved, and turned upſide down ſo that the tomentoſe ſurface is the lower. Heads ſimple, terminating, ſeſſile, the ſize of peas.

4. Stems ſhrubby, proliferous, rod-like, a foot and half high; with filiform branches, covered with preſſed-cloſe leaves. Leaves ovate-lanceolate, ſeſſile, ciliate, naked without, tomentoſe within, erect, and preſſed cloſe to the branches. Heads terminating, hemiſpherical, white, compoſed of many calyxes. Flowers ſeſſile, in bundles. Calyxes ſmooth, white, with lanceolate-ſubulate ſcales without a ray. Corollet ſingle, white. Stamens white. Seed crowned with ſix feathered briſtles. It has the habit of Xeranthemum capenſe [o].

In Syſtema Vegetabilium it is remarked, that the common calyx is ſubpentaphyllous and many-flowered, bell-ſhaped, and collected into a ball.

5. This reſembles the preceding very much, but differs in having the leaves unarmed not cuſped; and the flowers in heads, not umbelled. Both are ſingular for their lanceolate leaves preſſed cloſe, without convex and ſmooth, within channelled and white-tomentoſe.

6. This has the habit of a Heath in the herb.

7. This and the preceding were firſt obſerved at the Cape by Thunberg.

8. This forms the principal food of the Rhinoceros, whence it bears the ſame name among the inhabitants of the Cape.

9. This, with all the preceding ſpecies, is a native of the Cape of Good Hope [p].]

PROPAGATION AND CULTURE.

Theſe ſhrubby plants may be propagated by cuttings or ſlips, planted in july upon a bed of ſoft loam, and covered cloſe down with a bell or hand-glaſs, ſhading them from the ſun till they have taken root; then gradually inure them to the open air, and afterwards take them up, and plant them in pots, placing them in the ſhade till they have taken new root: then place them in a ſheltered ſituation with other tender exotic plants, and in autumn remove them into the dry ſtove.

DESCRIPTION, &c.

This plant has a corolla reſembling that of the common Blue-bottle (Centaurea Cyanus), with almoſt the calyx of Carthamus, to which genus it is allied [*].

Native of South Carolina. Introduced about 1766, by Mr. James Gordon. It flowers in auguſt [†].]

STOVES or Hot-houſes are buildings erected for preſerving ſuch tender exotic plants, as will not live in the reſpective countries where they are introduced, without artificial warmth in winter.

Though there is a great variety of theſe Stoves, yet they are reducible to two, the dry Stove and the bark Stove. [They are both comparatively of modern invention; the firſt not having been in uſe above one hundred and twenty years, and the latter being much poſterior to that.

Gerarde and Parkinſon, who wrote in the times of Queen Eliſabeth and King James the firſt, frequently uttered complaints that they were not able to retain many of the plants which they have taken the pains to introduce, during the ſeverity of our winters.

The former, under the article Cucumbers, in his Herbal printed in 1597, gives full directions for making a hot-bed, or as he calls it, "a bed or bank of hot and new horſe dung, taken forth of the ſtable, and not from the dunghill, wherein to ſet or ſow Cucumbers, Muſke melons, and other cold ſeedes, as alſo whatſoever ſtrange ſeedes are brought unto us from the Indies or any other hot regions. The which bancke you ſhall cover with hoopes and poles, that you may the more conveniently cover the whole bed or bancke with mats, old painted cloth, ſtrawe or ſuch like," &c. p. 764.

One cannot but ſmile to read in Parkinſon's *Paradiſus Terreſtris* or Garden of pleaſant Flowers, publiſhed in 1629, that the Laurel, which was then a curioſity, and called the Bay Cherry, was "defended from the bitterneſſe of the weather in winter, by caſting a blanket over the toppe thereof." P. 401.

It was cuſtomary at that time to place tender plants during winter in a cellar, to protect them from froſt. Of the *Canna indica*, or Indian flowering Reed, the ſame author ſays, it "doth not abide the extremities of our winters, eyther abroade or under covert, unleſſe it meete with a ſtove or hot-houſe, ſuch as are uſed in Germany, or ſuch other like place: for neyther houſe nor cellar will preſerve it, for want of heate." p. 376. We are not to conclude from hence that what we now call Stoves or Hot-houſes, were at that time known in England; but only that German ſtoves were ſometimes introduced into rooms, to warm them.

The uſe of bell-glaſſes for covering Melons came in between the times of Gerarde and Parkinſon. The latter recommends a hot-bed to be made in the ſame

[n] Linn. mant. [o] Idem. [p] Linn. ſuppl.

[*] L'Heritier. [†] Hort. kew.

Digitized by Google

manner as directed by Gerarde for raiſing the ſeeds, and alſo ridges whereon to tranſplant them, " at the leaſt two yards in ſunder, every one as it were in a hole, with a circle of dung about them, which upon the ſetting, being watered with water that hath ſtood in the ſunne a day or two, cover them with ſtrawe—ſome uſe great hollow glaſſes like unto bell heads," &c. p. 466.

" If any be deſirous," ſays Parkinſon, " to keepe the Orenge tree, he muſt ſo provide for it, that it be preſerved from any cold, either in the winter or ſpring, and expoſed to the comfort of the ſunne in ſummer. And for that purpoſe ſome keepe them in great ſquare boxes, and lift them to and fro by iron hooks on the ſides, or cauſe them to be rowled by trundels, or ſmall wheeles under them, to place them in an houſe, or cloſe gallerie for the winter time: others plant them againſt a bricke wall in the ground, and defend them by a ſhed of boardes, covered over with ſeare-cloth in the winter, and by the warmth of a ſtove, or other ſuch thing, give them ſome comfort in the colder times: but no tent or meane proviſion will preſerve them." p. 584.—See the account of Sir Francis Carew's Orange trees under *Citrus*.

In this ſtate, the means of protecting exotic plants continued during the greater part of the ſeventeenth century. Little or nothing ſeems to have been done in the time of the Commonwealth, when a general attention was paid to ſubjects of more immediate utility, ſuch as the introduction of Turneps and Clover, and the improvement of our huſbandry on the Flemiſh model.

More care was beſtowed upon the luxury of plants, as it may be called, after the Reſtoration; but I do not know that any Stove or Hot-houſe, properly ſo called, was erected before the year 1684.*

Sir Hans Sloane, in a letter to Mr. Ray, dated November 11, that year, informs him that Mr. Watts (gardener at the Apothecaries garden at Chelſea) had a new contrivance, at leaſt in this country; viz. he makes under the floor of his greenhouſe a great fire-plate, with grate, aſh-hole, &c. and conveys the warmth through the whole houſe, by tunnels; ſo that he hopes, by the help of weather-glaſſes within, to bring or keep the air at what degree of warmth he pleaſes, letting in upon occaſion the outward air by the windows. He thinks to make, by this means, an artificial ſpring, ſummer and winter.

In a ſecond letter, dated Dec. 20, he ſays, that he was yeſterday at Chelſea garden to ſee how the plants were preſerved there in the cold weather, and found, that in the day-time they put no fire into their furnaces, and that in the night they not only put in ſome fire, but cover the windows where they ſtand with pitch'd canvaſs, taking this off, and opening them as much as the air or wind permits.

In a third letter dated march 7, 1684-5, Sir Hans again ſays, that he was the other day at Chelſea, and found that the artifices uſed by Mr. Watts had been very effectual for the preſervation of his plants, inſomuch that the winter, which was ſevere enough, had killed ſcarce any of his fine plants[q].

This converſion however of the Greenhouſe into a Stove does not ſeem to have become common. Mr. Evelyn, in his *Kalendarium Hortenſe* or Gard'ner's Almanac recommends, " if the ſeaſon proves exceeding piercing, to kindle ſome charcoals, and when they have done ſmoaking, to put them in a hole ſunk a little into the floor of your Greenhouſe, about the middle of it: unleſs it have a *ſubterranean Stove*, which moderately, and with judgment tempered, is much to be preferr'd." In the mean time he wiſhes that ſome curious perſon would make trial of a greenhouſe and furnace, with earthen pipes to introduce warm freſh air, of which he gives a detailed deſcription accompanied with figures[r].

Mr. Bradley, in his New Improvements of Planting and Gardening, ſays that " Greenhouſes, as they are commonly built, ſerve more for ornament than uſe; their ſituation to receive the ſouth ſun being the only thing that ſeems to be regarded towards the health of the plants they are to ſhelter. It is rare to find one that will keep a plant well in the winter, either by reaſon of their ſituation in moiſt places, their want of glaſſes enough in the front, the diſproportion of the room within them: and ſometimes where it happens that a Greenhouſe has been well conſidered in theſe points, all is confounded by the flues under it, which convey the heat from the Stoves."

He then proceeds to inform us, that " beſide a Greenhouſe, it has been cuſtomary to provide Glaſs-caſes of ſeveral kinds, and Stoves for the preſervation of plants brought from different countries." But he condemns theſe as unneceſſary expenſes; and affirms that " a good Greenhouſe, well contrived, will do all that is required for the welfare of any plant in the winter." He deſcribes ſuch a Greenhouſe, and thinks that it may protect plants from all climates, by diſpoſing them judiciouſly, thoſe from the parts near the line in the warmer; and the others in the cooler parts of the houſe, introducing charcoal fires occaſionally in ſevere weather; or one of the new invented chimnies ſo judiciouſly improved by Mr. Deſaguliers, and deſcribed by him in his book called *Fires Improved*[s].

This idea of having one houſe for ſheltering plants of all climates, may ſerve to ſhew how imperfectly the ſubject was underſtood at this time.

At the end of this book, Bradley gives the deſcription of a Greenhouſe, accompanied with plan, elevation and ſections, contrived by Galilei, with a cupola in the middle, and a room at each end, having chimneys, to warm the rooms, and to convey warm air to the plants.

The ſame author, in his general treatiſe of Huſbandry and Gardening for the month of july 1724, p. 178. deſcribes a Stove or Conſervatory lately built (1721) by Mr. Fairchild at Hoxton, with flues and every thing in the modern form of a Dry Stove. It was ten or twelve feet in depth, and about forty feet in length: and had frames covered with glaſs in front, for tender bulbs and flowers.

Having thus brought down the hiſtory of dry Stoves to a period within the recollection of ſome perſons now living, we may proceed to Mr. Miller's account of their ſtructure and uſe.]

The Dry Stove may be either built with upright and ſloping glaſſes at the top; or elſe the front glaſſes, which ſhould run from the floor to the cieling, may be laid ſloping at an angle of 45°, the better to admit the rays of the ſun in ſpring and autumn, when the ſun declines. The latter method was formerly followed by many; but where I have had the contrivance of Stoves of this kind, I have always built them, after the model of the Bark Stove, with upright glaſſes in front, and ſloping glaſſes over them, becauſe this will more readily admit the ſun at all the different ſeaſons; for in ſummer, when the ſun is high, the top glaſſes will admit the rays to ſhine almoſt all over the houſe; and in winter, when the ſun is low, the front glaſſes will admit its rays; whereas when the glaſſes are laid to any declivity in one direction, the rays of the ſun will not fall directly on them above a fortnight in autumn, and about the ſame time in ſpring, and during the other parts of the year they will fall obliquely; and in ſummer, when the ſun is high, the rays will not reach above five or ſix feet from the glaſſes. Beſides, the plants placed towards the back part of the houſe, will not thrive in the ſummer ſeaſon for want of air; whereas when there are ſloping glaſſes at the top, which run within four feet of the back of the houſe, theſe, by being drawn down in hot weather, will let in air perpendicularly to all the plants; and of how much ſervice this is, every one who has had an opportunity of obſerving the growth of plants in a Stove, will eaſily judge; for when plants are placed under cover of a cieling, they always turn themſelves towards the air and light, and thereby grow crooked; and if, in order to preſerve them ſtraight, they ſhould be turned

[q] Ray's letters, 172, 173. 176.

[s] P. 197. ed. 3. 1719.

Digitized by Google

every week, they will ſtill be feeble, and look pale and ſickly.

If the ſituation be dry, the floor of the Stove need not be raiſed more than four feet above the level of the ground; but if it be wet, it will be proper to raiſe it three feet, eſpecially if the flues are to be carried under the floor. For if theſe be placed upon the ſurface, they will not draw ſo well as when they are more raiſed. The furnace muſt be placed at one end of the houſe; and the ſize of it muſt be directed by the kind of fuel intended to be burnt: if for coals or wood, it may be made according to the common method for coppers, only much larger, becauſe as the fire is to be continued chiefly during the night, if there be not room to contain a conſiderable quantity of fuel, it will want frequent attendance, and conſequently there will be great hazard of its being neglected. But if the fuel intended be turf, then the furnace may be the ſame as will be directed for the bark ſtove.

The flues are either carried under the pavement of the floor, or along the back of the houſe, over each other, and are returned ſix or eight times the whole length of the Stove, according to the height. If they are under the pavement, they may be carried ſtraight, or in a waving line; which latter, ſome think, will draw better, and they may be ſo much turned, as to reach almoſt from the back to the front of the houſe.

The depth of them ſhould not be leſs than eighteen inches, and the width nearly equal, which will prevent their being choaked up with ſoot, as is often the caſe when the flues are made too ſmall. The ſpaces between the flues ſhould be filled up either with dry brick rubbiſh, lime or ſand, from which little moiſture will ariſe; and the flues ſhould be cloſely plaſtered with loam both within and without, and the upper part covered with a coarſe cloth under the floor, to prevent the ſmoke from getting into the houſe. When the flue is carried from the furnace to the end of the houſe, it may be returned in the back above the floor twice in ſtraight lines, which may be contrived to appear like a ſtep or two, by which means the ſmoke will be continued in the houſe until all its heat is ſpent, which will conſequently warm the air of the houſe better: and the chimneys through which the ſmoke is to paſs off, may be either at both ends, or in the middle, carried up in the thickneſs of the brick work of the flues, ſo as not to appear in ſight within the houſe. The flues ſhould be firſt covered with broad tiles ſixteen inches long, and then a bed of ſand laid over them about two inches thick, upon which the other tiles ſhould be laid to correſpond with the reſt of the floor. This thickneſs of cover will be full enough to prevent the too ſudden riſe of the heat from the flues.

But if the furnace be placed under the floor, the thickneſs of ſand between the brick arch which covers it and the floor, ſhould not be leſs than four or ſix inches, ſo that the bottom of the furnace ſhould be ſunk the lower; and if from the fire-place to the end of the houſe the flues be laid a little riſing, it will cauſe them to draw the better; but this riſe muſt be allowed in the placing them lower under the floor next the fire, becauſe the floor muſt be laid perfectly level, otherwiſe it will appear unſightly.

In this Stove there ſhould be a ſtand or ſcaffold erected for placing ſhelves above each other, that the plants may be diſpoſed ſo as to make a handſome appearance in the houſe: but theſe ſhelves ſhould be made moveable, ſo as to be raiſed or ſunk, according to the various heights of the plants, otherwiſe it will be very troubleſome to raiſe or ſink every particular plant according to their heights, or every year as they advance in their growth. In placing the feet of this ſtand you muſt be careful not to ſet them too near the fire, nor directly upon the top of the flue, eſpecially that end next the fire; leſt by the conſtant heat of the tiles the wood ſhould take fire. The ſtand ſhould be in the middle of the houſe, leaving a paſſage about two feet and a half in the front, and another of the ſame width in the back, the more conveniently to paſs round the plants in order to water them, and that the air may freely circulate about them. In diſpoſing the plants, the talleſt ſhould be placed behind, and the ſhorteſt in front, ſo that there will not be occaſion for more than five or ſix ſhelves in height at moſt; but the ſcaffold ſhould be ſo contrived, that there may be two ſhelves in breadth laid upon every riſe, whenever there may be occaſion for it, which will ſave much trouble in diſpoſing the plants.

[Bark Stoves were of later introduction, as was obſerved above, than theſe Dry Stoves, which were only an improvement upon the old Greenhouſe, by adding more glaſs, and a furnace with flues. It ſeems probable that the culture of Ananas firſt gave riſe to the introduction of the Bark Stove. See TAN, or TANNER'S BARK.

Mr. Bradley, in his general treatiſe of Huſbandry and Gardening, for june 1724, p. 161, ſays, that "beſides the hot-bed commonly made of horſe-litter, there is another ſort frequently uſed in Holland, made of Tanner's bark; and that one of the beſt examples in England of this ſort is that of Mr. Henry Telende, gardener to Sir Matthew Decker at Richmond, for the propagating of the Ananas or Pine Apple, which has never been brought to perfection in Europe, till of late years Mr. Le Cour of Leyden found out their way of management with ſo much judgment, that he has ſeldom fewer than ſix or ſeven hundred plants in a ſummer, which bring perfect ripe fruit. To this gentleman's curious diſcovery we are at preſent obliged; for by imitating his method of cultivating this delicious fruit, we find there are like to ripen forty fruit-trees, this autumn in the garden at Richmond, which I have mentioned above; and I doubt not but in a few years we ſhall find them in like perfection in many of our Engliſh gardens."

In the ſame volume, for the month of july, p. 206, &c. Mr. Bradley gives a deſcription of the Pine Apple, the introduction of it into Holland by Mr. Le Cour, and its culture at Sir Matthew Decker's. He ſays that there were, in the Amſterdam gardens about two hundred plants, chiefly from Surinam and Curaçao, but ſome from the Dutch factories in the Eaſt Indies, which were in good health; but the art of bringing them to fruit was not known till Mr. Le Cour took them in hand. He thus deſcribes the hot-bed and frame, "for the education and ripening this fruit. His frame is made of whole deal, cloſely jointed: the length eleven feet, divided equally into four lights; the width ſeven feet and a half; three feet high at the back, and about ten inches in the front. The pit is ſomewhat more than five feet deep in the ground; the ſides are lined with brick, and the bottom is covered with pebbles. About the middle of february, he puts in as much hot dung or horſe-litter, as will raiſe the bed about a foot high, and then lays on the tanners bark as equally as poſſible, till the caſe of brick-work is filled, beating down the tan gently with a prong, or preſſing it down eaſily with a board. A bed of this kind will take up three hundred buſhels of tan, and if it be well made, will heat in about fifteen days, provided the frame and glaſſes are ſet over it. When the bed breaths a right heat, which we are to judge of by a thermometer, the plants are brought from the ſtove to it, either to have their pots quite plunged into the bark; or, if upon opening the holes for them, the bark be found too hot, then to be ſet in only half way, laying a few pebbles under the bottom of each pot, that the water may paſs freely through them. Care muſt be taken not to remove the pots in froſt or ſnow; and to examine the bed from time to time, whether the bark grows mouldy, muſty, or dry, which it will often do in the ſummer: in ſuch caſe, it muſt be watered to recover its heat. A bed thus prepared and managed will maintain a conſtant degree of heat, ſufficient to give theſe plants the utmoſt vigour they require, from the end of febuary to the end of october; and then the plants muſt be again removed into the ſtove or conſervatory. In exceſſive heats the glaſſes are tilted up at the back of the frame; and when the evenings are cool, the bed muſt be carefully covered with ſubſtantial mattreſſes of ſtraw. A bed of this kind ſinks about a foot, which is convenient, for otherwiſe the plants would

Digitized by Google

would be too tall for the frame, before the time of housing them."

"By the same method of culture, all such plants as are natives of climates as hot as Jamaica, the Caribbee islands, and two or three degrees more south, would prosper here as well as the Pine Apple. The Guava for instance, the Banana, Plantains, and even the Mango, with all the Spices." Experience has not justified this assertion of Professor Bradley's.

"The Stove used was that with iron plates over the flues; which, for greater warmth, was covered thick with thatch, and the glasses were well guarded with shutters; and that the fire might be constant, he burnt only such turf as is commonly used in Holland, agreeable to Mr. Le Cour's method."

"The thermometer used by Mr. Telende, had a tube twenty-four inches long, and one-eighth of an inch in diameter. When the spirit rose only to fifteen inches, he accounted the air cold for his plants; at sixteen and a half temperate; at eighteen warm, which was his standard for Pine Apple heat; at twenty inches, hot air; and at twenty-one inches, sultry."

In vol. 3 of the same work, for the month of july 1722, p. 51. Mr. Bradley says, that "the late instance of bringing the Ananas or Pine Apple to perfection in England, by the ingenuity of Mr. Telende at Sir Matthew Decker's, has so far gained upon the curious, that already many of our nobility have undertaken the same improvement; and 'tis not to be doubted but a year or two more will make this undertaking much more general."

In the same volume, for august, &c. p. 133. it is said, that "Mr. Telende's extraordinary success has encouraged many to undertake the culture of the Anana.—And that the new frame at the Physick Garden at Chelsea, wherein only the use of the Tanners Bark has been try'd this summer, 1723, by Mr. Miller the curious gardener there, is an instance, that it is not impossible to bring plants of the latitude of 18 or 20 degrees to the utmost perfection. About the beginning of august he observed the Sensitive plants there, about seven feet high, in blossom, and the Humble plants preparing to put forth their flowers. The Flower-Fence (Poinciana), so much esteemed in Jamaica, and some other plants of the same country, were said to be in greater strength than in Jamaica itself, considering the time of their growth from seed."

"As for Pine Apples, we have instances of their being brought to extraordinary perfection at the garden of the right honourable Spencer Compton, Speaker of the House of Commons, at Chiswick; and at that curious gentleman's Mr. John Warner, at Rotherhith. There are several Stoves now built by curious gentlemen on this account; but as they have not yet been proved, I shall forbear to mention them particularly, only to take notice, that that which was erected this summer in the gardens of William Parker, Esq. near Croydon in Surrey, commands the admiration of all the judges that have seen it, for just architecture, and good contrivance; the design of it, besides the keeping of tender plants during the rigour of our winters, and the restoring of sick plants, which is common to most stoves, is likewise to ripen some fruits, which have been ripened in other stoves here, as well as in Holland, and to make new experiments on others that have not been try'd; 'tis therefore endeavoured to make this stove capable of being heated differently in different parts of it, in order to imitate in some sort different climates, which may be regulated according to different heights of the thermometer. For these purposes it is so contrived, that in the summer time it may be useful by means of tanners bark only, and in the winter, both bark and fire may be used together, or fire alone."

"I observe," says he, "in a Stove, which Mr. Fairchild has built this year in his garden at Hoxton, for Pine Apples and the most tender plants, that he has raised his fire-flues above the surface of the floor of the stove: by which means he avoids all danger from damps."

The above account is accompanied with a plan and elevation of a Stove, with a pit for tanners bark, from a draught by Mr. Rogers of Shoe-lane, a very ingenious architect.

John Cowell, in his Curious and Profitable Gardener, Lond. 1730, oct. p. 27, gives the same account with Mr. Bradley of the cultivation of the Ananas or Pine Apple in Holland, and by Sir Matthew Decker in England; "where," says he, "they were so extremely well managed, that all gentlemen who had eat of them abroad, allowed them to be as good and as large as they found in the West Indies. This soon encouraged many of our nobility and gentry to build stoves and glass-cases for the culture of the Pine Apple, and they are now (1730) found in almost every curious garden."

"When I say," adds Mr. Cowell, "the first that were cultivated in England, were in Sir Matthew Decker's gardens at Richmond, I mean the first that were cultivated with success, were in those gardens; for long before we had plants of them brought to us, but had not before that time conveniences for bringing them to fruit, or even of keeping the plants alive."

Having thus ascertained the introduction of Bark Stoves, and established their use, let us proceed to Mr. Miller's account of their structure and management.]

The other sort of Stoves are commonly called bark Stoves, to distinguish them from the dry Stoves already mentioned. These have a large pit, nearly the length of the house, three feet deep, and six or seven feet wide, according to the breadth of the house, which pit is filled with fresh tanners bark to make a hot-bed, and in this bed the pots of the most tender exotic trees and herbaceous plants are plunged. The heat of this bed being moderate, the roots of the plants are always kept in action, and the moisture detained by the bark, keeps the fibres of their roots in a ductile state, which in the dry Stove, where they are placed on shelves, are subject to dry too fast, to the great injury of the plants. In these Stoves, if they are rightly contrived, may be preserved the most tender exotic trees and plants, which, before the use of the bark was introduced, were thought impossible to be kept in England; but, as there is some skill required in the structure of both these Stoves, I shall not only describe them as intelligibly as possible, but also annex plans of both Stoves hereto, by which it is hoped every curious person will be capable of directing his workmen in their structure.

The dimension of these Stoves should be proportioned to the number of plants intended to be preserved, or the particular fancy of the owner, but their length should not exceed forty feet for one fire-place; but where there are two fires it will be proper to make a partition of glass in the middle, and to have two tan-pits, that there may be two different degrees of heat for plants from different countries (for the reasons before given in the account of dry Stoves;) and were I to erect a range of Stoves, they should be all built in one, and only divided with glass partitions, at least the half way toward the front, which will be of great advantage to the plants, because they may have the air in each division shifted by sliding the glasses of the partitions, or by opening the glass door which should be made between each division, for the more easy passage from one to the other.

These Stoves should be raised above the level of the ground, in proportion to the dryness of the place, for if they are built on a moist situation, the whole should be placed upon the top of the ground, so that the brick-work in front must be raised three feet above the surface, which is the depth of the bark-bed, whereby none of the bark will be in danger of lying in water; but if the soil be dry, the brick-work in front need not be more than one foot above ground, and the pit may be sunk two feet below the surface. Upon the top of this brick-work in front must be laid the plate of timber, into which the wood-work of the frame is to be mortised; this should be of sound Oak felled in winter, without sap, the dimension one foot wide, and six inches deep, and the upright timbers in front must be placed four feet asunder, or somewhat more, which

Digitized by Google

which is the proportion of the width of the glaſs doors or ſaſhes; theſe ſhould be about ſix feet and a half, or ſeven feet long, and placed upright; their dimenſion ſhould be nine inches by ſix, of yellow Fir; but from the top of theſe ſhould be ſloping glaſſes, which ſhould reach within three feet of the back of the Stove, where there ſhould be a ſtrong crown-piece of timber placed, in which there ſhould be a groove made for the glaſſes to ſlide into; the dimenſion of the ſloping timbers ſhould be ten inches by nine of yellow Fir, and the crown-plate one foot by nine or ten inches of the ſame timber. The wall in the back part of the Stove ſhould be at leaſt thirteen inches thick, but eighteen or twenty-two inches, which is two bricks and a half, will be better, for the greater thickneſs there is in the back wall, the more heat will be thrown to the front, whereby the air of the Stove will be better warmed, and the building will be ſo much ſtronger; for to this back wall the flues, through which the ſmoke is to paſs, muſt be joined. This back wall ſhould be carried up about ſixteen or twenty feet high, or more for tall Stoves, that they may be of a proper height to ſupport the timbers of the back roof, which covers the ſhed behind the Stove. The roof is faſtened into the crown-piece before-mentioned, which in tall Stoves ſhould be about thirty feet above the ſurface of the tan-bed, which will give a ſufficient declivity to the ſloping glaſſes to carry off the wet, and be of a reaſonable height for containing many tall plants. The back roof may be ſlated, covered with lead, or tiled, according to the fancy of the owner; but the manner of the outſide building is better expreſſed by the annexed plan, than is poſſible to be deſcribed in words.

In the front of the houſe, before the tan-bed, there ſhould be a walk, about two feet wide, for the conveniency of walking; next to which the bark-pit muſt be placed, which ſhould be in width proportionable to the breadth of the houſe. If the houſe is fourteen feet wide, which is a due proportion, the pit may be eight feet wide, and behind the pit ſhould be a walk two feet wide, to paſs, in order to water the plants, &c. then there will be two feet left next the back wall to erect the flues, which muſt be all raiſed above the level of the bark-bed. Theſe flues ought to be one foot wide in the clear, that they may not be too ſoon ſtopped with the ſoot, as alſo for the more conveniently cleaning them; the lower flue, into which the ſmoke firſt enters from the fire, ſhould be two feet deep in the clear; this ſhould be covered with broad tiles, which ſhould be a foot and a half ſquare, or one foot by a foot and a half long, that they may be wide enough to extend over the wall in front of the flues, and to take ſufficient hold of the back wall; over this the ſecond flue muſt be returned back again, which may be twenty inches deep, and covered on the top as before; and ſo in like manner the flues may be returned over each other ſix or eight times, that the heat may be ſpent before the ſmoke paſſes off. The thickneſs of the wall in front of theſe flues need not be more than four inches, or three will do very well if they are carefully carried up, but it muſt be well jointed with mortar, and pargitered within ſide to prevent the ſmoke from getting into the houſe: the outſide ſhould be faced with mortar, and covered with a coarſe cloth, to keep the mortar from cracking, as is practiſed in ſetting up coppers. If this be carefully done, there will be no danger of the ſmoke entering the houſe, which cannot be too carefully guarded againſt, for there is nothing more injurious to plants than ſmoke, which will cauſe them to drop their leaves, and, if it continue long in the houſe, will entirely deſtroy them.

The fire-place muſt be made at one end, where there is but one; but, if the Stove is ſo long as to require two, they ſhould be placed at each end of the ſhed, which muſt be made the length of the Stove, that the fires and the back of the flues may not ſuffer from the outer air; for it will be impoſſible to make the fires burn equally, where the wind has full ingreſs to it, and it will be troubleſome to attend the fire in wet weather, where it is expoſed to the rain.

The contrivance of the furnace muſt be according to the fuel which is deſigned to burn, but as turf is the beſt firing for Stoves, where it can be had cheap, many prefer it, becauſe it laſts longer than any other ſort of fuel, and ſo requires leſs attendance. I ſhall deſcribe a proper ſort of furnace for that purpoſe.

The whole of this furnace ſhould be erected within the houſe, which will be a great addition to the heat, and the front-wall on the outſide of the fire-place, next the ſhed, ſhould be three bricks thick, the better to prevent the heat from coming out that way. The door of the furnace, at which the fuel is put in, muſt be as ſmall as conveniently may be to admit of the fuel; and this door ſhould be placed near the upper part of the furnace, and made to ſhut as cloſe as poſſible, ſo that there may be but little of the heat paſs off through it. This furnace ſhould be about twenty inches deep, and ſixteen inches ſquare at bottom, but may be ſloped off on every ſide, ſo as to be two feet ſquare at the top, and under this furnace ſhould be a place for the aſhes to fall into, which ſhould be about a foot deep, and as wide at the bottom of the furnace; this ſhould alſo have an iron door to ſhut as cloſe as poſſible, but juſt over the aſh hole, above the bars which ſupport the fuel, ſhould be a ſquare hole about four or ſix inches wide to let in air to make the fire burn: this muſt alſo have an iron frame, and a door to ſhut cloſe when the fire is perfectly lighted, which will make the fuel laſt longer, and the heat will be more moderate.

The top of this furnace ſhould be nearly equal to the top of the bark-bed, that the loweſt flue may be above the fire, ſo that there may be a greater draught for the ſmoke, and the furnace ſhould be arched over with bricks. The beſt materials for this purpoſe are what the bricklayers call Windſor bricks, which ſhould be laid in loam of the ſame kind as the bricks are made with, which, when burnt by the fire, will cement the whole together, and become like one brick; but you ſhould be very careful, wherever the fire is placed, that it be not too near the bark-bed, for the heat of the fire will, by its long continuance, dry the bark, ſo that it will loſe its virtue, and be in danger of taking fire; to prevent which, it will be the beſt method to continue a hollow, between the brick-work of the fire and that of the pit, about four or five inches wide, which will effectually prevent any damage ariſing from the heat of the fire; nor ſhould there be any wood-work placed near the flues, or the fire-place, becauſe the continual heat of the Stove may in time dry it ſo much as to cauſe it to take fire, which ſhould be very carefully guarded againſt.

The entrance into this Stove ſhould be either from a green-houſe, the dry Stove, or elſe through the ſhed where the fire is made, becauſe in cold weather the front-glaſſes muſt not be opened. The inſide of the houſe ſhould be clean and white-waſhed, becauſe the whiter the back part of the houſe is, the better it will reflect the light, which is of great conſequence to plants, eſpecially in winter, when the Stove is obliged to be ſhut up cloſe.

Over the top ſliding-glaſſes there ſhould be either wooden ſhutters, or tarpaulins fixed in frames to cover them in bad weather, to prevent the wet from getting through the glaſſes, and to ſecure them from being broken by ſtorms of hail, and theſe outer coverings will be very ſerviceable to keep out the froſt; and if in very ſevere cold there is a tarpaulin hung before the upright glaſſes in the front, it will be of great ſervice to the Stove, for then much leſs fire will preſerve a heat in the houſe.

In the warmeſt of theſe houſes or diviſions ſhould be placed the moſt tender exotic trees and plants. Theſe, being natives of very warm countries, ſhould be plunged in the bark-bed, and over the flues may be a conveniency made to ſet the Melon Thiſtle, the tender ſorts of Cereuſes, and Euphorbiums, with other very tender ſucculent plants, which require to be kept dry in winter.

As in this Stove are placed the plants of the hotteſt parts of the Eaſt and Weſt Indies, the heat ſhould be kept up equal to that marked Anana upon the botanical thermometers, and ſhould never be ſuffered to

Digitized by Google

be above eight or ten degrees cooler at moſt; nor ſhould the ſpirit be raiſed above ten degrees higher in the thermometer during the winter ſeaſon, both which extremes will be equally injurious to the plants.

But in order to judge more exactly of the temper of the air in the Stove, the thermometer ſhould be hung at a good diſtance from the fire; nor ſhould the tube be expoſed to the ſun, but, on the contrary, as much in ſhade as poſſible; becauſe, whenever the ſun ſhines upon the ball of the thermometer but one ſingle hour, it will raiſe the liquor in the tube conſiderably, when perhaps the air of the houſe is not near ſo warm, which many times deceives thoſe who are not aware of this.

In the management of the plants placed in the bark-bed, there muſt be a particular regard had to the temper of the bark, and the air of the houſe, that neither be too violent; as alſo to water them frequently, but ſparingly in cold weather, becauſe when they are in continual warmth, which will cauſe them to perſpire freely, if they have not a proper ſupply to anſwer their diſcharge, their leaves will decay, and ſoon fall off. As to the farther directions concerning the culture of the particular plants, the reader is deſired to turn to their ſeveral articles, where they are diſtinctly treated of.

In the erection of theſe Stoves, it will be of great ſervice to join them all together with only glaſs partitions between them, as was before obſerved: and where ſeveral of theſe Stoves and green-houſes are required in one garden, then it will be very proper to have the green-houſe in the middle, and the Stoves at each end, either placed obliquely or carried on in one ſtraight front. See the plan and elevation of the Conſervatory and Stoves, under *Conſervatory*, in the article GREENHOUSE.

By this contrivance in the ſtructure of theſe houſes, a perſon may paſs from one to the other of them, without going into the open air; which, beſides the pleaſure to the owner, is alſo of great uſe, becauſe there will be no occaſion to make a back-way into each of them, which otherwiſe muſt be, ſince the front glaſſes of the Stove ſhould not be opened in cold weather, if it can poſſibly be avoided on any account, otherwiſe the cold air ruſhing in, will greatly prejudice the very tender plants.

But beſides the Stoves here deſcribed, and the green-houſe, it will be very neceſſary to have a glaſs-caſe or two, wherever there are great collections of plants. Theſe may be built exactly in the manner already deſcribed for the Stoves, with upright glaſſes in front, and ſloping glaſſes over the top of them, which ſhould run within four feet of the back of the houſe. The height, depth, and other dimenſions, ſhould be conformable to that of the Stoves, which will make a regularity in the building. Theſe may be placed at the end of the range on each hand beyond the Stoves; and if there be a flue carried along round each of theſe, with an oven to make a fire in very cold weather, it will ſave a great deal of labour, and prevent the froſt from ever entering the houſe, be the winter ever ſo ſevere; but the upper glaſſes of theſe houſes ſhould have either ſhutters of wood, or tarpaulins in frames to cover them in froſty weather; and if there is a contrivance to cover the upright glaſſes in froſt, either with mats, ſhutters, or tarpaulins, it will be of great uſe in winter, otherwiſe the flue muſt be uſed when the froſt comes on, which ſhould only be done upon extraordinary occaſions; becauſe the deſign of theſe houſes is, to keep ſuch plants as require only to be preſerved from froſt, and need no additional warmth; but at the ſame time, require more air than can conveniently be given them in a greenhouſe. In one of theſe houſes may be placed all the ſorts of Aloes, Meſembryanthemums, African Sedums, Cotyledons, and other ſucculent plants from the Cape of Good Hope. In the other the ſeveral kinds of Arctotis, Oſteoſpermum, Royena, Lotus, and other woody or herbaceous plants from the ſame country, or any other in the ſame latitude.

Thus by contriving the greenhouſe in the middle, and one Stove and a glaſs-caſe at each end, there will be a conveniency to keep plants from all the different parts of the world, which can be no otherwiſe maintained but by placing them in different degrees of heat, according to the places of their native growth.

The Stoves before deſcribed are ſuch as are uſually built to maintain exotic plants, which will not live in England, unleſs they enjoy a temperature of air, approaching to that of the ſeveral countries from whence they are brought; and whoever is inclinable to preſerve a large collection of plants from different countries, muſt contrive to have two or three of theſe Stoves, each of which ſhould be kept in a different temperature of warmth; and the plants ſhould be adapted to the ſeveral degrees of heat required to preſerve them; but as the far greater number of Stoves which have been erected in England, are deſigned for the culture of the Ananas only, I ſhall add a deſcription of two ſorts of Stoves, of the leaſt expenſe in building for this purpoſe; ſo that whoever is inclinable to erect a Stove for ripening Ananas, may, by attending to the plans and deſcriptions, direct the building and contriving ſuch Stoves as they are deſirous to have, or according to the number of fruit propoſed to be ripened annually.

The firſt ſort of Stove is that which is deſigned for the plants, which produce the fruit the ſame year; for as the plants do not generally fruit until the ſecond year from their being taken from the old plants, whether they are ſuckers from the ſide of the plants or crowns taken from the fruit, if they fruit the ſucceeding year, the fruit will be ſmall; therefore when they are properly managed, they will not produce their fruit until the ſecond year, by which time they will have obtained ſtrength to produce large fruit, in which their greateſt value conſiſts; for although there are ſeveral varieties of this fruit, which differ in degrees of goodneſs, as in moſt other fruits, yet they may all of them be improved in their ſize, without diminiſhing their excellence in taſte; though I know there are ſome perſons of a contrary opinion, and who believe that the ſmall fruit are always better flavoured than the large; but from long experience I can aſſert, that the larger and better nouriſhed this fruit is, the higher will be its flavour, ſuppoſing the ſorts are the ſame; therefore every perſon who cultivates this fruit, ſhould endeavour to have it improved to the greateſt perfection; in order to which it will be proper to have a ſmall Stove, in which the young plants may be placed to bring them forward for fruiting, and the following autumn they ſhould be removed into the larger Stove for ripening; but I ſhall return to the deſcription of the larger Stove. The length of this muſt be proportionable to the quantity of fruit deſired in one ſeaſon, for as to the width, that ſhould not be much varied; the tan-bed ſhould never be narrower than ſix, nor ſhould it be more than ſeven feet wide; for when it is more, there will be difficulty in reaching thoſe plants which are in the middle of the bed, to water or clean them; and if there is room enough on each ſide of the bed for a walk a foot and half broad, it will be ſufficient for perſons to water and do every thing which is neceſſary to the plants; and as theſe places are not deſigned for walking in, it is to no purpoſe to have broad walks; and the fires muſt be larger, in proportion to the ſpace of the houſe, otherwiſe the air cannot be kept in a proper temperature of warmth. If the Stove is made thirty-ſix feet long in the clear, then the tan-bed may be thirty-three feet long, and a walk left at each end a foot and half wide, which will be ſufficient to walk round the bed to water and attend the plants; and ſuch a tan-bed will contain eighty fruiting plants very well if the bed is ſeven feet wide, and this Stove may be very well warmed with one fire; but if the Stove is built much larger, there muſt be two fire-places contrived, one at each end, otherwiſe the air of the houſe cannot be kept in a proper temperature of heat. The quantity of fuel which will be wanting for a Stove of thirty-ſix feet long in the clear, is about three chaldron and a half of coals, or in ſuch proportion for any other ſort of fuel; when coals can be had reaſonable, it is the beſt kind of fuel; and the pit or Scotch coal is preferable to the Newcaſtle

Digitized by Google

coal, becauſe the latter is very ſubject to melt or run into clinkers when the oven is very hot, which the pit coal never does, but always burns away with a white aſh, making but little ſoot; ſo that the flues will not require to be ſo often cleaned, as when the other coal is uſed. The next beſt fuel for Stoves is peat, where it can be procured good, but the ſcent of this fuel is diſagreeable to many people. There are ſome perſons who burn wood in their Stoves, but this fuel requires much greater attendance than any other, therefore is not very proper for this purpoſe; but in the building of the Stoves, the ovens muſt be contrived for the ſort of fuel which is to be uſed in them.

The Stoves deſigned for ripening the fruit of the Ananas ſhould have upright glaſſes in their front, which ſhould be high enough to admit a perſon to walk upright under them on the walk in the front of the houſe; or where this cannot be admitted, the front walk may be ſunk one foot lower than that on the back of the tan-bed, ſo that the ſurface of the bed will be a foot above the walk, which will be rather an advantage, as the plants will be ſo much nearer the glaſs; and a perſon may with great eaſe water and attend the plants when they are thus raiſed above the walk; therefore, when a Stove is ſo ſituated, as that the raiſing of it high above ground might be attended with inconvenience, the walks quite round the tan-bed may be ſunk a foot or eighteen inches below the top of the bed, which will admit of the Stove being built ſo much lower; for if there is height for a perſon to walk under the glaſſes, it will be as much as is required; but as the flues, when returned four times againſt the back wall will riſe near ſeven feet, ſo the bottom of the lower flue ſhould be on the ſame level with the walk, to admit room enough for the whole under the roof. Over the upright glaſſes there muſt be a range of ſloping glaſſes, which muſt run to join the roof, which ſhould come ſo far from the back wall as to cover the flues, and the walk behind the tan-pit; for if the ſloping glaſſes are of length ſufficient to reach nearly over the bed, the plants will require no more light; therefore theſe glaſſes ſhould not be longer than is abſolutely neceſſary, that they may be the more manageable.

The other Stove (commonly called the Succeſſion Houſe), which is deſigned for raiſing young plants until they are of a proper ſize to produce fruit, need not be built ſo high as the former, the frames therefore may be made in one ſlope, without any upright glaſſes in front: many perſons have formerly made tan-beds, with two flues running through the back wall, and covered with glaſſes, made in the ſame manner as thoſe for common hot-beds, only larger. But thoſe, having no paſſage into them, the glaſſes muſt be taken off when the plants want water, &c. The damps alſo often riſe in winter, when the glaſſes are cloſely ſhut. And there is danger of the tan taking fire, where great care is not taken that it does not lie near the flues. So that although the ſmall Stove (or ſucceſſion houſe) here propoſed, is more expenſive in building, yet being greatly preferable to thoſe pits, and the after expenſe being the ſame, it has become more general wherever this fruit has been cultivated.

Where there is no danger of the wet ſettling in winter about the tan, the bark-pit may be ſunk two feet deep in the ground, and raiſed one foot above the ſurface. The only walk which is neceſſary in theſe Stoves, is at the back of the bed, and that may be on a level with the ſurface of the ground, ſo that the tan-bed will be more than a foot above the walk; and the flues beginning from the level of the walk, there will be room to return them three times, which will warm the air much more with the ſame fire than when they are carried but twice the length of the Stove.

But in wet land the tan-bed ſhould be wholly raiſed above the level of the ground, in order to preſerve the tan from being chilled by moiſture; and in ſuch places the walk at the back ſhould be raiſed near two feet above the level of the ground, becauſe the tan-bed ſhould not riſe much more than one foot above the walk; for if it is higher, it will be more difficult to reach the plants when they require water. The brick wall of the pit, on the ſide next the walk, need not be more than four inches thick, ſo far as riſes above the walk, but below that it ſhould be nine inches thick: the reaſon for reducing the wall above, is to gain room for the walk, which would otherwiſe be too much contracted; and if there is a kirb of Oak laid on the top of the four inch wall, it will ſecure the bricks from being diſplaced, and ſufficiently ſtrengthen the wall, which being but one foot above the walk, will not be in any danger of falling; and on this kirb there may be two or three upright iron bars fixed with claws, to ſupport the crown-piece of timber, which will ſecure it from hanging in the middle. There may be more or fewer of theſe bars according to the length of the Stove; but if they are about ten feet aſunder, it will be near enough. If theſe iron bars are one inch ſquare, they will be ſtrong enough to anſwer the deſign.

[Hot-houſes and Pine-Stoves are frequently infeſted with red ſpiders, ants and other inſects. A kind of bellows has been invented, and is ſold in the ſhops, by which the fumes of burning tobacco are applied to the plants; or when the houſe is deeply infected, it may be filled entirely by means of a hole made in the door big enough to admit the pipe of the bellows; the ſmoke being kept in for ſeveral hours. This muſt be repeated two or three times, according to the condition the plants are in; but if ſome few only are infected, they may be removed into a ſmall room and fumigated there. This operation is found to anſwer well in forcing-frames, hot-beds, on Melon-plants, &c. The inventor Mr. Green, at the royal garden at Kew, received a premium from the Society for the encouragement of Arts, &c. for this invention.

Matches alſo, moiſtened with a tincture of Aſſa-fœtida, and then rolled in a powder of brimſtone and Scotch ſnuff in equal quantities, have been recommended to be burnt in the houſes cloſe ſhut up. The walls alſo, with the frames, &c. to be well waſhed with four ounces of ſublimate diſſolved in two gallons of water. This waſh may be uſed on old garden walls, and to the roots of trees infeſted with ants, if made weaker[t].

Forcing Stoves are a modern invention for bringing forward before the natural ſeaſon all ſorts of elegant flowers and delicate fruits. They differ in no wiſe from thoſe which are deſcribed above in their ſtructure and manner of being heated, but only in their application.

The bark forcing Stove has a tan-pit, in which pots of Roſes, Pinks, Narciſſuſes and other bulbs, and various choice flowers are plunged, in order to have them early in the ſpring. Tender annual flowers may alſo be raiſed in this pit. And pots of Strawberries, dwarf Cherries, Kidney Beans, &c. may either be ſet in the pit, on the ſides of it, or on ſhelves nearer to the glaſſes. If the Stove be big enough, there may be a border of earth next the back wall, and a ſmall one in front, in which fruit-trees, ſuch as Cherries, Peaches, Nectarines, and Apricots, may be planted in the full ground. Vines alſo, planted on the outſide in front, may be trained in, along the frames of the upper ſaſhes. This Stove has a furnace with flues, and gentle fires muſt be made in this when the nights are cold, and even in the day time occaſionally, when the weather is very ſevere, to keep a uniform heat.

The dry forcing Stove has no pit, but furnace and fire-flues only; and is intended chiefly for forcing fruit-trees, as Peaches, Nectarines, Vines, Figs, early Cherries, and the beſt ſorts of Apricots and Plums, together with Gooſeberries, Currants, Raſpberries, Strawberries, &c.—The whole area is filled with rich earth two feet deep, in which the trees are planted to remain, having been firſt trained in the open ground, till they are in a ſtate for bearing. They are planted

[t] Weſton's Tracts, ed. 2. p. 296. and Ailway in Tranſ. Arts, vol. 5.

in

in ſtraight or oblique lines from the back to the front, the talleſt behind; and are trained againſt the back wall and front to a trellis, and in the area as eſpaliers. Pots of Strawberries and Kidney-Beans are placed upon ſhelves near the glaſſes, and Vines are trained in from without along the frames, or on trellis-work over the upper glaſſes.

Theſe Stoves begin to be worked in january or early in february. When the fruiting ſeaſon is paſt, the upper glaſſes are removed, to admit air and ſhowers, to ſtrengthen the annual ſhoots of the trees; and ſo continue till winter.

It is obvious, that in ſuch a Stove, crouded with fruit-trees of different kinds, that require different management, and ſome more warmth to force them than others, all the trees will not ſucceed equally well; and the Vines trained along the upper glaſſes will be apt to ſhade the trees in the area below too much. Curious and opulent noblemen and gentlemen therefore have a diſtinct Stove conſtructed for each ſort of fruit; taking its name from the ſpecies of fruit which it is deſigned to bring forward: as the Peach-houſe, Vinery, &c. But ſince there is nothing peculiar in the ſtructure of theſe Stoves, and they differ chiefly in the uſe to which they are applied, it is not neceſſary to deſcribe them.

Stoves upon various plans, according to the fancy of the owner or the builder, have been conſtructed; but as in general there is little to recommend them, and the common ones are the beſt for uſe, it would be loſing time to enter farther upon the ſubject.

Forcing-Frames are much uſed by the nurſery-men near London for bringing forward or forcing early flowers, tender annuals, dwarf fruit-trees, Strawberries, Kidney-beans, &c. Theſe are from five to fifteen feet wide, from five to ten feet high, and of any length at pleaſure; a wall of brick behind, and a front of glaſs, either in one ſlope, or with upright glaſſes before, and ſloping ones above. Dung, bark, or fire may be applied to heat theſe forcing-frames. If the firſt, it is placed chiefly againſt the back wall and ends, which are then moſtly formed of thick planks. If bark or fire be uſed, the ſtructure and application are much the ſame as in the Bark and Dry Stoves deſcribed above.

Hot-walls are forcing-frames worked by fire, and intended to bring forward choice fruits. If it is propoſed to have only a ſingle row of trained trees, a border of from four to ſix feet in width will be ſufficient. The back wall muſt be eight or ten feet high, with flues running the whole length. In front is a wall a foot high, with a plate on it; upon which are ſloping glaſs-frames, to the top of the back wall; theſe are moſt convenient in two ranges, the upper range made to ſlide. The trees are trained on a trellis, within five or ſix inches of the wall. Along the bottom may be ſet in the border Strawberries, dwarf Kidney-beans, frame Peas, Roſes, or any flowers or fruits, that do not grow ſo high as to ſhade the trees. Such a frame may be worked with one furnace, if it be not more than forty or fifty feet long.

Larger forcing-frames differ in nothing from the Forcing Dry Stove deſcribed above.

For Hotbeds, ſee the article in its proper place, and under CUCUMIS.]

Frames covered with oiled paper inſtead of glaſs, are ſometimes uſed for protecting Melons, &c. They may be made either like the cover of a waggon, or like the roof a houſe. They have a frame of wood at the baſe, to which, in the former, broad hoops are faſtened bent over circularly. The width of the frame ſhould be from five to ſix feet. The diſtance between the hoops ſhould not be more than a foot; and there ſhould be two rows of ſtrong packthread or rope yarn on each ſide of the arch, running from hoop to hoop, to keep the oiled paper from ſinking down with wet. The length of each frame ſhould not be much more than ten feet, that being about the ſize of a three-light frame; and if they are longer, they will be ſo heavy as to be troubleſome to move.

The other ſort of frame may be made of pantile laths, or ſlips of deal of thoſe dimenſions, faſtened into a ridge-tree at the top, and the baſe-frame at the bottom. The lights may have hinges alternately on each ſide, that they may be raiſed to give air occaſionally, on the ſide from the wind, or on both ſides when the weather is warm.

When the frames are quite dry, the paper is paſted on. The beſt paper for this purpoſe, is what they call Dutch wrapper; for it is ſtrong, and when oiled over becomes pellucid. After the paſte is well dried, the paper ſhould be oiled over on the outſide, which if well done with lintſeed oil will be ſufficient. The oil ſhould be dry before the frames are expoſed to the wet, otherwiſe the paper will tear. In paſting the paper on the frames care ſhould be taken to ſtretch it out very ſmooth; and to paſte it to all the ribs of the frames, and alſo to the packthreads, to prevent the wind from raiſing the paper.

If the frames are well painted over with the following compoſition, they will laſt a long time.—To every ſix pounds of melted pitch, add half a pint of lintſeed oil, and a pound of brickduſt; mix them well together, and uſe them warm. This is the beſt pigment for all timber expoſed to the weather, for no moiſture can penetrate through it.

The covers here deſcribed muſt not be kept too cloſe down over the plants, leſt they be drawn up too weak: but air ſhould always be admitted, when it can be done with ſafety.

Theſe covers of oiled paper are uſeful not only for Melons, but for covering cuttings of exotic plants, and for many other purpoſes. The paper will ſeldom laſt longer than one ſeaſon; but if the frames be well made, and when out of uſe, carefully laid up under ſhelter, they will laſt ſeveral years; eſpecially if a band of ſtraw be laid round the bed, for the frames to reſt upon, during the time they are in uſe.

DESCRIPTIONS, &c.

1. Leaves all radical, forming a ſtar-like tuft, as in the Aloes and Sedums: their ſubſtance is rigid, brittle, vaſcular and pellucid; their teeth and points very ſharp; the keel alſo ſharp. Peduncles ſeveral, ſhorter than the leaves, upright, ſomewhat compreſſed, ſmooth; each bearing one upright white flower, ariſing from a two-leaved ſheath. Stamens ſhort, with awl-ſhaped anthers. Germ above the ſheath, but much below the calyx. Styles ſix, cloven, riſing a little above the ſtamens[u]. Berry ovate, beaked, drooping, fleſhy: cells with a double membrane, very thin, ſeparate lengthwiſe, full of a cryſtalline pulp. Seeds from ten to twelve in each cell, ovate, ſomewhat angular, of a pale, browniſh red, neſtling in the pulp, and faſtened to the rind of the berry, near the external angles of the cells. The pulp in its natural ſtate is clear, like the vitreous humour of the eye; in ſpirits of wine it becomes opaque and white, like the white of an egg when boiled; plunged into water it becomes clear again[x].

The Stratiotes, Water Aloe or Water Soldier, is a ſtoloniferous plant, and truly perennial, though each root flowers but once, as in ſome ſpecies of Saxifraga, Sempervivum, &c. The parent plant, rooted in the mud at the bottom of the ditch after flowering, ſends out buds of leaves at the end of long runners, which riſe to the ſurface, form roots, flower, and then ſink to the bottom, where they take hold of the mud, ſometimes ripen their ſeeds, and always become in their turn the parents of another race of young offsets.

Linneus quotes Bergen, Zinn and Fabricius, as having found the flowers dioicous; (he ſays alſo that Schreber ſent him a male flower, and obſerved that in the hermaphrodite flower the anthers were barren: accordingly he has placed this plant in the claſs Dioecia.) Linneus however always obſerved them to be hermaphrodite. The ſtamens are apparently imperfect in ſome flowers, and the ſtyles in others. The genus is very near akin to Hydrocharis, and perhaps ought to be united with it[y].

Native of ſome parts of Europe, and of Siberia. In England, it occurs plentifully in the fen ditches of the Iſle of Ely. In Lincolnſhire and Norfolk very frequent. In Cheſhire and Yorkſhire. Flowering in july. In ſpring the offsets riſe and float on the ſurface, ſometimes eight or ten in a circle, and ſo thick, as entirely to fill up the ſurface of the ditches, and prevent all other plants from growing in it. A great variety of inſects are nouriſhed by this plant; ſome of them purſue it down to the bottom of the water, and devour the leaves[z].

2. Root creeping, little branched, jointed as in Acorus. Leaves radical, cluſtered, linear, margined, rounded at the point, quite entire, ſubſerrate towards the point, ſomewhat coriaceous, four feet long: margin raiſed, blunt, very ſmooth: ſheaths membranaceous, very tender, growing to the leaves. Scape among the leaves, quite ſimple, ſolitary, erect, filiform, thickened towards the flower, ſmooth, naked, three or four feet high, one-flowered. Spathe linear, compreſſed, browniſh green, two-leaved: leaflets membranaceous, ſpreading, folded together, blunt, with the keel bearded with fibrils towards the point. Flower ſuperior. Perianth three-leaved, ſhorter than the corolla: leaflets concave, membranaceous, duſky green with blood-red ſpots. Petals three, linear, acute, waved with tranſverſe plaits, flaccid, white ſtained with red, eſpecially at the points. Filaments ſcarcely any. Anthers twelve, linear, acuminate, compreſſed, alternately ſhorter, without dotted blood-red, on the inner ſide green, hirſute. Germ inferior, linear, compreſſed, imbricate on all ſides with fringed ſcales, green yellowiſh at the baſe. Fruit an ovate drupe, compreſſed, hirſute with fibres, the ſize of a hen's egg, four or ſix-celled. Seeds fourteen or more.—Native of the Ceyloneſe iſlands. Found by Koenig[a].

3. Spathe one-leafed, with five, membranaceous, longitudinal angles[b]. According to Forſkahl, the flowers have only ſix ſtamens; ſtyles ſix, bifid.—— Native of the Eaſt Indies and Egypt.]

PROPAGATION AND CULTURE.

1. Young plants muſt be procured in ſpring, when they firſt riſe on the ſurface of the water, and placed in canals, ponds or large tubs or ciſterns, where they will ſtrike down their roots, and increaſe without farther care.

2. Strelitzia auguſta.
Lin. ſpec. ed. Willd. 1. 1190. *Thunb. prodr.* 45.
Leaves ribbed netted-veined.

DESCRIPTIONS, *&c.*

1. All the leaves radical, petioled, oblong, quite entire, with the margin at bottom waved and curled, very ſmooth, glaucous beneath, coriaceous, a foot long, permanent. Petioles ſomewhat compreſſed, three feet long and more, the thickneſs of the thumb, ſheathing, erect, ſmooth. Scape the length and thickneſs of the petioles, erect, round, covered with alternate, remote, acuminate ſheaths, green with a purple margin. General ſpathe a ſpan long, green on the outſide, purple at the edge; partial ſpathes whitiſh. Petals yellow, four inches long. Nectary blue [c].

The ſpathe, ſays Mr. Curtis, contains about ſix or eight flowers, which becoming vertical as they ſpring forth, form a kind of creſt, which the glowing orange of the corolla, and fine azure of the nectary, render truly ſuperb.

The ſpecific character of Heliconia alba in Linneus's Supplement (p. 157.) belongs to that plant, but the trivial name, to another African ſpecies, not yet to be met with in the gardens of Europe [d].

The name of Thunberg's prodromus (p. 45) belongs to this ſpecies; but not the ſpecific character. It is deſcribed in the Supplement under the name of Heliconia Bihai [e].

Native of the Cape of Good Hope. Introduced in 1773, by the Right Hon. Sir Joſeph Banks. It flowers here in april and may. John Miller's figure was drawn from a plant that flowered in the Pine-ſtove of Bamber Gaſcoyne, Eſq. Mr. Curtis's figure was taken from another plant which flowered in the bark ſtove of the garden at Chelſea, belonging to the Apothecaries Company [f].

2. The ſpecific character in Thunberg's prodromus, of his Strelitzia auguſta; and of Heliconia alba in Linneus's Supplement, do not belong to this plant. But the diagnoſis of Heliconia Bihai in the latter work does.

The leaves of Strelitzia, Heliconia, Muſa, and the plants of the Scitamineæ order are not properly nerved, but have parallel ribs.

Native of the Cape of Good Hope [g].

PROPAGATION AND CULTURE.

It may be propagated by ſeeds or by the roots; but ſeeds do not ripen readily in England, and it increaſes very ſlowly here by the roots. It has been uſually plunged in the tan-pit in a ſtove: but when the roots are thus confined, the plant rarely or never flowers. When the roots have by accident extended into the rotten tan, it has readily thrown up flowering ſtems; the beſt practice therefore is to let the roots have plenty of earth to ſtrike into. Being a Cape plant, it may probably be found to ſucceed beſt in the dry ſtove or conſervatory [h].

STREPTIUM. (*From* στρεφω, *verto, flecto, torqueo: whence* στρεπλος, *verſatilis, flexilis, tortilis: flexible or twiſting.*)

Roxb. corom. t. 146.

Claſſ. 14. 2. Didynamia Angioſpermia.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, oblong, bellied, five-angled, five-grooved, five-toothed, covered with ſtiff white hairs, permanent, cloſing and enlarging with the fruit, which it entirely covers.

COR. one-petalled: tube cylindric, rather longer than the calyx, twiſted near the apex, a little curved: border five-parted; diviſions obovate, equal.

STAM. *Filaments* four, in the upper bent part of the tube: two longer and two ſhorter. *Anthers* round, two-lobed, approaching by pairs.

PIST. *Germ* ſuperior, four-lobed. *Style* length of the tube. *Stigma* large, two-lipped: the upper very ſhort; the under long, broad, recurved.

PER. *Drupe* dry, two-lobed, hid in the withered inflated cloſed calyx, nut-like, laterally echinate: each lobe bipartile.

SEEDS one in each diviſion of the nut, oblong, tapering towards the end, a little bent.

ESSENTIAL CHARACTER.

Cal. five-toothed. *Stigma* two-lipped. *Drupe* two-lobed, each lobe bipartile.
